The fruit staged was superior in many respects, the Apples and Pears specially fine. Vegetables were not up to the usual standard of excellence. For six dishes of dessert Apples there were ten lots. Mr. Geo. Goldsmith, Leonardslee, Horsham, was first with very highly coloured fruits, having very choice Blenheim Orange, Cox's Orange, King of Pippins, Mother Apple, Adams' Pearmain, and rather uneven Ribstone, Mr. Turton, Reading, being a very close second, having grand fruits of Rosemary Russet, Jefferson, King and Cox's Orange Pippins. For cooking Apples, six dishes, the awards were reversed, Mr. Turton leading easily with splendid fruits of Emperor Alexander, Peasgood's Nonsuch, Cox's Pomona, Mère de Ménage, Prince Albert, and Bedfordshire Foundling. Mr. G. Goldsmith was a good second, his best dishes being Lord Derby, Warner's King, Gascoigne's Scarlet, and Peasgood's. For six dishes of dessert Pears, Mr. W. Allan, Gunton Park, Norwich, was an easy first out of ten lots staged, having very clear, large fruits, perfect in every way, Doyenné du Comice being especially fine, also Pitmaston, Durondeau, Emile d'Heyst, Marie Louise (a grand lot), and Marie Louise d'Uccle. Mr. Goldsmith was second, with equally fine Pitmaston, very fine Souvenir du Congrès, Beurré Diel, and General Todtleben. Grapes were not shown in large numbers. Mr. T. W. Hill, Rockshaw, Merstham, had the best three bunches of Gros Colman, the berries very fine and well coloured, Mr. W. Taylor, Tewkesbury Lodge, Forest Hill, being second, with larger bunches, but not well finished. For any other black Grape, Mr. Bury, Petersham Vineries, Byfleet, was an easy first out of four lots staged, having good shaped bunches, berries large and well coloured, the variety being Alicante. Mr. Taylor was second, with huge bunches, but lacking size of berry. For white Grapes, four lots were staged, Mr. W. Tidy, Stanmore, being an easy first with Muscat of Alexandria. For twelve varieties of Potatoes, Mr. Wiles, Farnborough, was first, showing very clean tubers, the varieties being Lord Tennyson, Mr. Breese, Satisfaction, Reading Ruby, Purple Perfection, The Dean, Trumps and seedlings, Mr. E. Chopping, Sittingbourne, being second. The same exhibitors in the order named secured the awards in the six dishes, very fine Snowdrop and Windsor Castle being staged in the first lot. The collections of vegetables, nine kinds, usually strongly contested, only brought five competitors, Mr. Waite, Esher, being first, his Intermediate Carrots, Ailsa Craig Onions, Prizetaker Leeks and Brussels Sprouts being his best dishes; Mr. R. Lye, Newbury, a close second, having excellent dishes, but overdone with roots. Messrs. Sutton, Reading, received a gold medal for a magnificent collection of Potatoes, most of the varieties being similar to those staged last week at the meeting of the R.H.S. Messrs. Cutbush, Highgate, had a large collection of fruit, having five Pears of the well-known kinds with some of the newer ones, in excellent condition, such as Le Lectier, Princess and Margaret Marillat (silver-gilt medal). Messrs. Lee and Sons, Ealing, had a collection of 100 varieties of Apples and Pears, Princess, Huyshe's Victoria, Beurré Alexandre Lucas and Directeur Alphan Pears being very fine (silver-

gilt medal). Messrs. Spooner and Sons, Hounslow, had a good collection of Apples and Pears, most of the well-known kinds being staged (silver medal). Mr. Berridge, Southall, had a collection of vegetables in variety, including climbing Bean Tender and True, Potatoes, Artichokes, Onions, Kales and salads (silver medal). Mr. Empson, Amptill House, Bedford, staged six varieties of Carrots, notable for their colour and shape.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 12, in the Drill Hall, James Street, Victoria Street, Westminster. The committees will meet as usual at 12 o'clock, and at 3 p.m. a lecture on "Substitutes for Larch" will be delivered by Dr. Maxwell T. Masters, F.R.S.

#### NOTES OF THE WEEK.

**Galanthus Olgae Reginae.**—To "F. W. B.'s" remarks on this, I may add that here it was out fully six weeks before *octobrensis*, which opened its first flower to day (October 30). Its bulbs are oblong, while those of *octobrensis* are round, suddenly tapering to the neck. It is difficult to judge bulbs and other plants fairly this year, because the season was adverse to their free development. *G. Olgae Reginae* ought to be cultivated one or two years more to form a definite decision as to its merits.—MAX LEICHTLIN, *Baden-Baden*.

**Begonia Triomphe de Lorraine.**—This is one of the finest of the winter-flowering section. I do not know its parentage, but it seems to be somewhat intermediate between the old favourite *B. weltoniensis* and *B. Martiana*. It is dwarf in habit; the flowers, which are produced in great profusion, stand well up above the foliage, forming a perfect ball of bright pink blossom almost entirely covering the small pale green leaves. The same plants will keep up a succession of bloom for many weeks. I have plants which have been in flower for fully two months, and they appear likely to continue some time longer yet.—H.

**Richardia Pentlandi.**—I am sending you a flower of the yellow *Richardia* from bulbs collected specially for the Hon. Walter Rothschild by my friend and schoolfellow, Mr. C. Ayres, nurseryman, of Cape Town. The bulbs were received from him early in April of this year as the variety *Pentlandi*. I have flowered several, and all of them have proved true to that name. I find that from amongst over 100 bulbs sent, a few of the spotted leaved kind (*R. Elliottiana*) have appeared. You will observe in the flower I send there is no crimson at the base, the colour being pure self yellow.—E. HILL.

**Frost in Notts.**—A frost of unprecedented severity for the time of year, and which was repeated for eight consecutive nights, has occurred in South Notts. The lowest figure to which the mercury fell was 20, or 12° of frost—this, unfortunately, catching everything when in a wet condition; 6°, 7°, and 8° were registered on other nights, the first being the lowest number of all. It is needless to say that gardeners and farmers were not at all prepared for such a sudden and severe change, and that many tender crops have suffered. A good many Potatoes were in the ground on allotments, and, of course, many of the uppermost tubers have been frozen. On Saturday, the 27th, from 3 inches to 4 inches of snow fell in some parts of the county, the woods and hills presenting a most wintery aspect.—J. C.

**Tropaeolum speciosum in Surrey.**—This year I have grown this north, south, east and west, and it has prospered everywhere, provided always that it had a free root-run and a good mulch of fresh road scrapings. On the east I had the finest plants and the finest flowers, owing to the

rich soil, but the great blaze was on a hot south border, where it ran up the wall and over the other plants, sometimes in patches and sometimes trailing along like fiery snakes. This plant likes fresh soil and to move itself to fresh quarters. The best plants are always those that have pushed themselves into pastures new. On the north there was a long distance between the flowers, and these came very late. On the west it did the worst, for the soil was not good, but still it grew some 6 feet and flowered.—J. WHITWORTH SHAW, *New Place, Lingfield*.

**Salvia azurea.**—There are a few species of *Salvia* which are very useful in the greenhouse for flowering during the rather dull time which comes just before the *Chrysanthemum* season. Three especially are worthy of recommendation: *S. Betheli*, with deep rose flowers, *S. splendens* var. *compacta*, with bright scarlet ones, and the subject of the present note, which has blue flowers. The last is rather a tall thin plant and grows 5 feet or even more high. That this habit can be taken advantage of in the grouping and arranging of the plants in the conservatory is well shown in No. 4 house at Kew, where *Salvia azurea* is grouped with some bush-grown white *Chrysanthemums*. Although the *Salvias* are not so full of flowers as they were a month ago, the thin, elegant stems, with their blue blossoms standing well above the white background of *Chrysanthemums*, make a charming arrangement. It is a plant of the easiest cultivation, and should be grown from cuttings every year. The plants ought to be well fed during the summer, and unless large plants are desired, the cuttings need not be rooted till May.

**Lapageria rosea in North Wales.**—By to-night's post I send a box of *Lapageria* blooms and foliage cut from a plant growing outdoors on the north side of a wall, but sheltered somewhat by high vinerias. The plant has been growing in its present position about eight years and is now quite acclimatised. The only protection I afford it in severe weather is a covering of old greenhouse shading. Previous to last winter the plant never suffered in the least, but the frosts of last February proved rather destructive to the soft and unripe wood, although all the matured wood came through the severe ordeal without injury. This is the more noteworthy, as *Laurustinus*, *Aucubas*, and various other plants in the same garden fared badly, whilst many plants of the double-flowering Gorse were killed outright. For vigorous growth, size and rich colour of the flowers, the plants grown indoors cannot in any way compare with the one the flowers sent were cut from.—R. W. NICHOLSON, *Bodlondeb, Conway, N. Wales*.

\* \* \* The most surprising thing we have seen for some time; the leaves large like those of a good Ivy, the flowers fresh and brilliant, and of stronger and better texture than when grown indoors.—ED.

**Epidendrum purum.**—Although in these days the genus *Epidendrum* is rather a despised one among Orchid-growers generally, it nevertheless contains a goodly number of really charming species. Amongst these the graceful *E. purum* may certainly be included, for its quiet beauty contrasts with and also enhances the more obtrusive beauties of the *Cattleyas*, *Dendrobiums*, &c., that flower along with it. The stem-like pseudo-bulbs are from 1 foot to 1½ feet high, as thick as one's thumb in the middle, but tapering to both top and bottom. The leaves are confined to near the top and are of narrow, lanceolate shape, and 6 inches to 7 inches long. The raceme branches into six or eight divisions and arches out from the top of the stem very gracefully. Each of the divisions of the raceme forms a pretty drooping spray about 10 inches long, on which the flowers are thickly borne; the latter are each about 1 inch across and of a clear, pale green colour. On first expanding, the flowers are fragrant, but afterwards become scentless. The species is a native of the mountains of Colombia, where it was discovered by Purdie, but, according to Messrs. Veitch, it had been known for some years previously, and was in cultivation in the

noted collection of Mr. Rucker at least fifty years ago. The flowers remain for several weeks in perfect condition, and plants that were in bloom in September still retain their attractions.

**Rhus typhina.**—Amongst the trees and shrubs cultivated for the autumnal colouring of their leaves, *Rhus typhina* (the Stag's-horn Sumach) deserves a prominent place. It is a small tree or large shrub, with large and striking pinnate leaves 2 feet to 3 feet long, the leaflets being lanceolate, coarsely toothed, hairy, and numbering from ten to thirteen pairs (with an odd terminal one) on each leaf. During the summer they are of a rich deep green, but in autumn change to a dark crimson or purplish red. No shrub appears to colour with greater certainty and regularity, and this year, when many things have failed to put on their proper autumnal dress, this has been as richly coloured as ever. The recent sharp frosts have, however, prematurely destroyed its beauty. The species is a native of North America, extending from the Southern United States northwards to Canada. It is of rather crooked and ungainly growth when it reaches the adult stage, but when grown in a mass for autumn effect, it should be treated as *Paulownia imperialis* is sometimes done, and cut hard back each spring before growth commences, leaving one or two shoots only to each plant. By this means it is kept low, and the foliage is much larger than that of the full-grown tree.

**Elaeagnus pungens.**—This is one of the evergreen species of *Elaeagnus*, and in the south of England at any rate it is a really valuable and ornamental shrub. An evergreen it is a welcome contrast to the Pontic *Rhododendrons*, *Laurels*, &c., with which so many gardens are overburdened, but flowering as it does during October and November when pretty nearly everything else is preparing for the winter's rest, it ought to be doubly appreciated. The leaves are 1½ inches to 3 inches long, and, like the bark of the young branches, dark brown and scabrous. The upper surface of the leaves is a vivid, lustrous green, but they are beautifully silvery beneath; both surfaces are thickly pitted with small holes, but more especially the under one, which is also speckled with small darkly-coloured scales. The flowers are borne in short clusters in the axils of the leaves; they are pendulous, somewhat bell-shaped, and resemble tiny *Fuchsia* flowers, the perianth being only three-eighths of an inch long. In colour they are of nearly the same shade of silvery grey as the under surface of the leaves. Their greatest charm, however, as hardy shrubs in flower in November is the rich powerful fragrance, very much resembling that of the *Gardenia*. The species is a native of Japan, and there are several very handsome variegated forms of it in cultivation. A fine specimen is in flower near the Palm house at Kew. Close to it is one also of the nearly allied *E. glabra*; this, too, is in bloom.

**Angræcum bilobum.**—Among small-growing Orchids no group is so charming as the dwarf *Angræcums*. Such species as *A. Sanderianum*, *A. citratum*, and others are now fairly well known in British collections. The reverse is the case, however, with *A. bilobum*, which is now in bloom at Kew. It is rare and very pretty, and at the same time quite distinct. It is, like nearly all the *Angræcums*, a native of tropical Africa, being found in the Cape Coast (Castle region). Although so uncommon in cultivation, it was introduced over fifty years ago, and was figured by Dr. Lindley in his *Botanical Register* in 1841. The most distinctive character of this *Angræcum* is its foliage; the leaves are about 2 inches long and of a dark shining green, speckled with dull purple dots. They are quite narrow at the base, but widening upwards to the broad, unequally bi-lobed apex. The flowers occur on slender, drooping racemes and are of a pure glistening white. As is the case with several other *Angræcums*, the parts of the flower are alike in shape and almost so in size, the lip being only slightly larger than the sepals. The flowers, of which

half a dozen or more are borne on one spike, are each a little over 1 inch across, the pale green spur being about twice as long. This species, as may be judged from its habitat, requires warm, moist treatment. Most of these small *Angræcums* are happiest under the treatment given to *Phalænopsis*, and, on the whole, few Orchids need more care than they do to keep them in health for many years after importation.

**A fine Todea superba.**—A plant of this has been under my care for the last twenty-seven years, and a few remarks as to the treatment it has had may not be out of place. A very small plant was obtained for fifteen shillings. It was carefully protected with a bell-glass and placed in a warm house, the compost used being fine peat with a good portion of sand; it was given plenty of water. As I found that this treatment did not answer, I repotted it in a good portion of *Sphagnum*, well dried, and gave less water at the root. It was kept constantly damp overhead and in a much cooler place, the bell-glass being discarded. With this treatment the plant got on well, and in two or three years I had to shift it into a 14-inch pan not more than 6 inches in depth, using the same material for potting. It is now in a cold pit with only a 5-inch wall. In the winter of 1878 we had 32° of frost, but with a little rough manure round and a couple of mats on the top, and though covered up for a fortnight, the plant was quite fresh. The next shift was into a 20-inch pan, using the potting material more lumpy than before. It is now in a house having a north aspect, but no heat. In three or four years it has made a mass of roots, running down outside the pan. The last shift given was into a pan 26 inches wide and about 8 inches deep. The foliage of five years' growth is quite fresh and completely covers the surface of the pan. The plant now measures 7 feet from tip to tip. A good supply of water is given when growing, but is discontinued in winter, so as not to excite the plant into growth before the proper season. The plant is syringed once or twice a day in summer and occasionally in winter. The thermometer last year fell to 9° below zero, and the only heat that reached the plant was through a door that opened into a house kept at 45°. A pan of *Trichomanes radicans* measuring 5 feet across standing near makes a good companion.—H. WAND, *Brinkburn, Darlington, Yorks.*

\* \* \* The photograph sent with the above showed a remarkably fine specimen of this Fern, proving that the treatment given suited it.—ED.

**The Tree Tomato.**—The Tree Tomato (*Cyphomandra betacea*) is, though perhaps not to be recommended for the flavour of its fruit when grown in the British Isles, a most handsome plant in appearance. In the winter of 1893 I received three seeds which had been brought home from Ceylon. In due time the plants appeared, and when about 2 feet high were planted out in a large span-roofed Tomato house. They grew at a prodigious rate, and by the autumn had reached a height of 10 feet and had opened a few clusters of whitish, solanaceous flowers at the extremity of the stalk, which up to within 1 foot of the top was branchless. Some of the leaves were very large, being 2 feet in length by over 1 foot in breadth, and possessed a most evil odour, inasmuch so that many persons found it necessary to thoroughly wash their hands after touching them. In the frost—no heat being kept in the house during the winter—the leaves died and the tops of the stems were cut off. This spring the plants sprouted all up the stem, and the lower growths being rubbed off, eventually formed large heads, which in time flowered and produced quantities of fruit. The latter was in clusters, the individual fruits being smooth and somewhat egg-shaped, more pointed at the apex than at the base, and turning a dull orange-red when presumably ripe. As far as my experience goes, the fruit is equally unpalatable whether cooked or raw. I understand that the plant is a native of South America, and was from there imported to Ceylon and India, where it is now common. It is distinctly striking and ornamental when laden with fruit and flowers,

its large leaves having quite a tropical effect, but nothing but discomfort is to be gained by handling it or partaking of the fruit.—S. W. F., *Torquay.*

**The weather in West Herts.**—A week of variable weather as regards temperature. During the night of the 2nd inst. the exposed thermometer showed 7° of frost, whereas three nights afterwards the same instrument never fell lower than 44°. Since the beginning of the week the temperature of the soil at 2 feet deep has risen 2°, and at 1 foot deep as much as 6°, and at the latter depth is now about seasonable. Rain has fallen on each of the last four days, and to the total depth of 1 inch, so that the ground is once more quite saturated. Yesterday (the 5th) was the most windy day for a month, and yet the wind at no time exceeded in strength what sailors would call a "fresh breeze," showing how calm the weather had previously been.—E. M., *Berkhamsted.*

## BOOKS.

**Les Azaleas.**\*—A handy book on Azaleas and their culture under glass and out of doors, including chapters on grafting, proper soils, manures, diseases and insects, the varieties of the plant and the best methods of packing for the market; also chapters on the so-called hardy Azalea of Ghent—*Azalea mollis* and *Azalea amara*.

**The New Forest.**†—This is an agreeable, chatty book on our most famous forest. There is no attempt to go deeply into the vexed question of forest management which occupies the attention of experts at the present time. The authors, too, make light of the historical account of the origin of the New Forest, and they have a somewhat far-fetched theory of their own to account for the death of the "Red King" while hunting among the New Forest glades, into which it is not necessary at this remote period to follow them. Apart from some unorthodox conjectures and speculations, the reader will find a good deal to interest him in the chapters which deal with the forest, its beauties, customs, sports, geology, inhabitants, fauna, flora, &c. Few will fail to sympathise with the authors' hope expressed in the concluding chapter that this beautiful region may never become another black country. Yet there appears to be some justification for the fear which is implied, since it is now a generally accepted belief that the New Forest forms a link in the chain of coalfields which once extended from Somersetshire to Belgium. It is to be hoped that having given us one charming volume on the New Forest, the authors will not allow their pens to grow rusty, but will follow it up with others on a subject which they know so intimately.

**Names of plants.**—*Lady Maitland.*—*Cattleya Dowiana.*—*F. S. Phillips.*—*Grevillea robusta.*—*Jones.*—*Brassavola cuspidata.*—*S. H. B.*—*Phlomis fru icosa.*—*Constant Reader.*—*Cotoneaster oëfnis.*—*Neil Sinclair.*—*Linaria vulgaris.*—*C. S. B.*—*Ilex latifolius.*

**Names of fruit.**—*H. P.*—1, Claygate Pearmain; 2, Striped Beaufin; 3, Rosemary Russet; 4, not recognised; 5, Pear Beurré Clairgeau; 6, Beurré Capiaumont.—*E. Semper.*—1, Marie Louise d'Uccle; 2, Winter Nells; 3, Beurré Rance; 4, Marie Louise; 5 and 6, next week.—*W. R. C.*—1, Sops in Wine; 2, Kerry Pippin.—*M. McMillan.*—1, Pear Marie Louise d'Uccle; 2, Marie Louise; 3, Souvenir du Congrès; 4, Vicar of Winkfield; 5, Catillac; 6, Apple Ribston; 7, not recognised; 8, Ecklinville; 9, Cellini; 10, Cox's Pomona; 11, Warner's King; 12, Lord Derby; 13, Small's Admirable; 14, King of the Pippins; 15, Wyken Pippin.—*J. O. M.*—2, Passe Colmar; 4, Doyenné Boussoch; 5, Beurré Bachelier.—*Nemo.*—1, Lord Sully; 2, Beauty of Kent; 3, Mère de Ménage; 4, not recognised; 5, Cox's Pomona; 6, Small's Admirable.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## STOVE AND GREENHOUSE.

## COLOUR IN CARNATIONS.

WITH reference to the catalogue descriptions of colours of Carnations and other plants, "E. J." in THE GARDEN (p. 299) complains that the descriptions are often misleading. No doubt this is so in many instances, but I do not think it is done with the intent to mislead. It is only those who have to describe new varieties who know the difficulty of properly giving the many shades found among Carnations. Besides this, opinions differ much as to the most correct definition of the various shades. I do not know the variety William Scott referred to by "E. J.," but with respect to Miss Joliffe being a good shade of pink there is little doubt, though I should describe it as flesh-pink. Mrs. Leopold de Rothschild is a difficult variety to describe. I have seen blooms of this which have been of quite a deep shade of rosy pink, while in some instances they have been even paler than those of Miss Joliffe. There are also other varieties which vary equally as much. In describing the colours of the various classes of plants, it becomes somewhat a matter of practice rather than accuracy. Take, for instance, the scarlet Sweet Pea or the scarlet Stocks; they certainly differ in colour from the scarlet Geraniums. Reverting to Carnations, the so-called crimson are perhaps as far from the mark as any. Take the deep claret-coloured Uriah Pike, Duke of York or Mrs. Homsley, they are all of too deep a shade for crimson proper. I herewith send you a bloom of Leonidas, which is to my idea the true crimson, though it might be described as deep scarlet. Taking colours as they are found in Carnations, there are many shades, yet it is possible to follow the source from which they are obtained. For instance, a pure white, crossed with bright scarlet, such as A. Aléga-tiere, will give the soft flesh-pink shades usually, while the whites crossed with purple will give the slate-coloured shades. Mrs. Llewellyn is quite a different shade of pink from that of Miss Joliffe, having a shading of purple in it. In Bouvardias we have some distinct shades of pink. In Priory Beauty there is a shading of purple, while Mrs. Robert Green has more of red shaded pink. This may be seen best under artificial light, the latter showing up much better than the deeper shade of Priory Beauty.

Although in so many plants we get such an enormous variety of shades, yet it is remarkable that yellow and blue are rarely met with in the same class of plants. The Pansies are the only instance I can recall where the two colours are found. The entire absence of blue in the Rose, Carnation, Dahlia and Hollyhock is remarkable, as almost every other conceivable shade of colour is found.

Perhaps the plant which has caused more disappointment with regard to colour than any other is the so-called blue Chinese Primula, which, when seen under the very best light possible, is of sombre appearance, and under the slightest disadvantage is not worth looking at. Curiously enough, there is not a good yellow Chinese Primula, though the deep yellow eye and the other yellow species would lead one to

suppose that there would be no difficulty in getting a good yellow. A. HEMSLEY.

**Cimicifuga simplex.**—*Cimicifuga racemosa*, a North American plant introduced into this country a century and a half ago, is the best known member of the genus, but there are other desirable kinds, and one bearing the name of *C. simplex* forms a very attractive feature in No. 4 house at Kew. The genus *Cimicifuga* is a near relative of the *Ranunculus*, but the plant in question has a good deal of the appearance of a strong-growing *Spiraea*. The large compound leaves are very much like those of *Spiraea Aruncus*, while the entire plant reaches a height of 5 feet or thereabouts. The white flowers are borne in branching panicles, and in many cases the closely packed blossoms extend for quite 9 inches along the spike. From the mass of protruding anthers a spike of blossom has a good deal the appearance of a Bottle-brush. As seen at Kew it is certainly a very desirable plant for the greenhouse or conservatory early in the autumn, at which time as a rule *Chrysanthemums* form the major part of the floral display, and the loose open habit of the *Cimicifuga* is in direct contrast to the more lumpy growth of the *Chrysanthemums*.—H. P.

**Coprosma Baueriana variegata.**—Twenty-five years ago or thereabouts, when this *Coprosma* was comparatively new, it was propagated as rapidly as possible by many of our leading nurserymen, as at that time plants with variegated foliage were extremely popular, and it was also adapted for the style of bedding-out then in vogue, that is in which long straight lines of one particular subject were used. Though occasionally employed as a bedding plant, it is not very much used for that purpose; indeed, many gardens may be visited without meeting with it. Still, it forms a very attractive shrub from a foliage point of view for the greenhouse, and one, too, that can if necessary be turned outside during the summer. If in good health, the bright shining green leaves with their decided variegation render it one of the most admired of greenhouse shrubs. It is not at all a difficult plant to propagate, especially if the stock plant is kept a little closer and warmer than usual. In a structure that is too cool to maintain a winter display of blossoms, such fine-foliaged plants as this *Coprosma* will present a cheerful appearance throughout the dull season. Another fine-foliaged plant well adapted for association with it is the Japanese *Eurya latifolia variegata*, a Camellia-like shrub, with its leathery leaves variegated in different ways with white and pink.—T.

**Alberta magna.**—This promises to be a decidedly ornamental shrub for the greenhouse—that is, if it blooms freely when large, for at present the plants of it to be met with are only small, and consequently do not flower much. It was very noticeable at Kew lately, and the blooms remained in perfection a considerable time. It is a free, upright-growing shrub, of sturdy habit, clothed with ovate leaves of a deep shining green, while the flowers, which are borne in terminal panicles, are individually tubular in shape, little more than an inch long, and of a very bright crimson tint. The large calyx lobes are said to change after the flowers have dropped to a bright red colour, thus forming another noticeable feature. This *Alberta* is a native of Natal, and was as a new plant distributed by Mr. William Bull, of Chelsea, in 1891. It succeeds well under ordinary greenhouse treatment, and with regard to soil, it prefers a fair proportion of peat and a good sprinkling of rough sand. Most of the earlier plants distributed were seedlings, and as cuttings can be struck it will perhaps after a time flower more freely in a small state than it does now. The weaker shoots make the best cuttings.—H. P.

**Veronica Purple Queen.**—This fine variety, which was sent out by Messrs. Veitch and Sons last year, has been flowering freely with me throughout the autumn. The plants were from cuttings struck early in April. It is a plant which requires very little skill to grow it success-

fully. The earlier in the year the cuttings can be put in the better. The young plants should be potted off singly as soon as they are well rooted. They require stopping about three times, and will then make fine bushy plants for 5-inch pots. After the final shift, the pots may be plunged in the open ground, or if planted out they will make good plants to take up and pot in the autumn, but then do not flower so freely as when grown in pots, especially if planted in rich soil. Although the colour is against it for some purposes, yet for the conservatory or window boxes it is very useful, and the pleasant perfume is a further recommendation. I may add that some plants standing in a sheltered position out of doors are quite unharmed by the recent frosts, though we have registered 12° and plants have been frozen through.—H.

## CROTONS.

THESE beautiful plants have in the past been much neglected, but they are now coming into favour again, as the fine displays which have been seen at various exhibitions during the season testify. As variegated-leaved plants *Crotons* undoubtedly hold first place, no other class of plants giving such a great variety of either form or shades of colour. Large specimens are very attractive when well grown, yet it is in the smaller sized plants that their beauty is seen to the greatest advantage, while such plants are also more useful. As table plants they are much in demand, and for this purpose the plants should not exceed 18 inches in height. The narrow-leaved varieties are most appreciated for table decoration, while the broad-leaved sorts are better adapted for grouping.

To grow *Crotons* successfully they require a high temperature and to be fully exposed to all the light obtainable, and though a little shading may be necessary during the hottest part of the day for a few weeks in the summer, the less they are shaded the brighter the variegation will be. If careful attention is paid to the watering and a moist atmosphere maintained, *Crotons* will withstand the brightest sunshine we get—that is, provided they have been grown on from the time of starting into growth in the spring under such conditions, but it would be fatal to plants which had been growing freely under shading to fully expose them when the growths are young and tender.

*Crotons* do not require much pot room—in fact, they are all the better for being confined to comparatively small pots, 4½-inch pots being quite large enough for plants from 18 inches to 2 feet high. They succeed in any ordinary compost, but good drainage should be given, and if grown in a light sandy compost they keep their variegation better than when in a richer soil. After the pots are well filled with roots, a little liquid manure may be used from time to time until the plants have made their growth. Cow manure and soot make the best liquid manure, but it should be made some time before it is required for use, so that it may settle down and be used when quite clear.

The best time for propagating *Crotons* is from now onwards to the end of January. If good-sized tops are taken from plants with well-matured growths they will root freely in the stove propagating pit. A little dry sand should be applied to the base of the cuttings as soon as taken off; this will prevent bleeding, and the cuttings will not be so likely to rot at the base. The cuttings should be kept quite close and shaded until they begin to make roots; with care large cuttings may be rooted without losing a leaf. One important matter is to keep the plants free from insect pests; like most plants requiring a high temperature, they are subject

to the attacks of thrips, red spider and other pests. If the plants are properly cleansed by sponging and fumigating, the syringe, if properly used, will go a long way towards keeping them clean afterwards.

#### VARIETIES.

These are so numerous and varied, besides which, when seen under different conditions they vary so much, that it is difficult to make a selection and keep within a reasonable limit. Many of the older sorts still hold their own. *C. majesticus*, for instance, is undoubtedly one of the best of the long, narrow-leaved varieties, and may always be relied on to colour well. *Angustifolius*, though more difficult to grow, is when well done one of the most beautiful. Countess and Superbus are both good narrow-leaved varieties and rarely run out of colour. Golden Ring is a newer variety, with long, narrow-twisted leaves, the variegation being of a rich golden hue. Flambeau is a very highly coloured variety, the deep golden variegation changing to a rich crimson hue. Ruberrimus is another good narrow-leaved variety, which changes to a rich crimson. Of broader leaved varieties which change to a ruddy hue, Musaicus, Etna, Formosus, Newman, Mortefontaineensis, Flamingo, Emperor Alexander III., and Gordoni are among the best. Of those which retain the yellow, Thompsoni is one of the most effective, and Mortefontaineensis is another which may be strongly recommended. Earl Derby, which has a broad linear marking of bright yellow, is very pretty, but rather inclined to revert to green. Warreni, Prince of Wales, Massangeanus, Bergmani, and Lady Zetland are others which should find a place in every collection.

Croton leaves are now much used for decoration, and most of those referred to above will be found very useful for the purpose. *Elegantissimus* often makes shoots with the terminal leaves pure golden yellow, and these may be used with fine effect in bouquets. H.

**Urceolina pendula.**—There is no danger of confounding this *Urceolina* with any other bulbous plant now in flower, as the blossoms are remarkably distinct, and at the same time very beautiful. Various notes on this plant have appeared from time to time in *THE GARDEN*, and a coloured plate of it was given May 12, 1888, but it is so charming just now as to well merit a passing notice. The foliage is very like that of the *Eucharis*, to which, indeed, it is closely allied, though in general appearance the flowers are very different, presenting as they do the appearance of an inverted urn. The body of the flower is of golden yellow colour, while at the mouth where the segments are divided it is green. The best time for repotting this *Urceolina* is early in the year, and after this the plants will still start into growth, and towards the end of the summer the leaves will die off. When this takes place water must be given more sparingly, but the soil must not be allowed to become too dry. After this the flower-spikes will soon make their appearance, but the plants are by no means regular in their blooming, which in a general way is an advantage, as their season of flowering is spread over a much longer period than would be the case if they all threw up their spikes at once. This plant, which is also known by the specific name of *aurea*, is a native of Peru, and was discovered by Mr. Pearce when travelling for Messrs. Veitch, of Chelsea, during the year 1863, and it first flowered in their establishment a year later. Its affinity to the *Eucharis* suggested to Messrs. Clibran a hybrid between the two, and *Urceocharis Clibrani* was the result. The flowers of the hybrid are in shape more like those of the *Urceolina*, while the colour is white, as in the other parent. It seems to bloom at various seasons of the year, but chiefly in

spring and early summer. When strong enough it is probable that flowers will be produced continuously for lengthened periods.—H. P.

**Siphocampylos Humboldtianus.**—Good plants of this will, if placed under favourable conditions, be very rarely without flowers at any season of the year. An illustration of this is to be found in the fact that, though frequently alluded to in the different horticultural publications as a summer-flowering plant, it is now blooming just as freely as it was in July, and bids fair to continue for months. It is also known as *S. fulgens*. When in good condition it forms a freely-branched plant of a half-shrubby character, clothed with dark green leaves and plentifully sprinkled with its bright scarlet tubular-shaped blossoms. A soil consisting of good loam with a liberal amount of leaf-mould and silver sand will suit it well. Liquid manure occasionally is also of great service, as a little additional stimulant applied in this way is better than putting the plants into large pots. *S. Humboldtianus* is a native of Peru, whence it was introduced in 1867. The temperature of an intermediate house will suit it best. Though the genus *Siphocampylos* consists of nearly 100 species, it is very rarely that any other kind besides that above mentioned is to be met with.—T.

**Acacia platyptera.**—There is no danger of confounding this *Acacia* with any other species, for the curiously winged stems are so very distinct, added to which it is now in flower, while the other members of the genus (or at least those in general cultivation) bloom in the spring. The wings, which are arranged on either side of the stems and branches, are green, and in some instances nearly half-an-inch wide. The flowers are disposed in the shape of little balls along the shoots and are of a bright golden yellow; they remain in perfection longer than those of the spring flowering members of the genus, and a succession is kept up for some time. This *Acacia* is a native of the Swan River district in Western Australia, and was introduced into this country in 1840. It is not very easily propagated from cuttings, and is also less vigorous in growth than many of the others.—T.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUMS AT TRENT PARK, BARNET.

In some notes referring to the chief exhibition at the Aquarium last year I stated that the first prize forty-eight Japanese blooms from Mr. F. Bevan, and staged by his gardener, Mr. W. H. Lees, were the finest ever exhibited. Inspecting the collection recently, I could not help observing the splendid growth of the plants. This is not, however, the time to speak much of cultural items, but I may say Mr. Lees takes each individual variety and adapts his mode of treatment to the constitution of the same. The result is very few mistakes indeed, and when it is borne in mind that Trent Park is very rich in novelties—that is, in sorts about which little was known before—such success is the more remarkable. It is of the lately-introduced *Chrysanthemums* I would like to make a few notes. In speaking of the size of any sort I may say the measurements are mental.

#### WHITE VARIETIES.

Mlle. M. A. DE GALBERT has a bloom 7 inches across and of similar depth, with rich, flat florets hanging in wave-like form. The colour is white and the quality is superb. I am pretty certain this variety will be more highly esteemed than is Mlle. Thérèse Rey. It was raised by M. Ernest Calvat.

MUTUAL FRIEND is an American-raised kind. The flowers are pure white; the florets wide,

thick and long, forming perhaps a somewhat flat bloom, but of very fine substance. The growth, too, is dwarf, and in other respects all that can be desired.

MME. CARNOT is a charming pure white, of exquisite formation. The bloom is large and of fine quality; the type is pure Japanese, that is, informal in arrangement, yet with a finished outline.

MME. AD. MOULIN.—This white, though in cultivation some time, is but little known; but when Mr. Lees' specimens are seen there will be many who wish to possess it. The variety has very long drooping florets, forming a mass over 6 inches across, the depth considerably more. It is a handsome flower, and the plant seems of easy growth.

MME. AD. CHATIN.—This is a beautifully formed, loosely incurved Japanese of immense size, pure sparkling white and of rich substance; undoubtedly the finest of this particular type. It is dwarf in growth.

SOUVENIR DE PETITE AMIE.—Another pure white handsome form. The petals reflex and build up a full massive blossom of large size, of notable substance, and richness of texture. Habit very dwarf. It may be well to note that late buds come best.

When such grand *Chrysanthemums* as the above become more widely known, the old sorts as *Avalanche*, *Stanstead White*, and so on will be discarded. That promising white of last year, *Philadelphia*, is not a success, nor does Mrs. C. E. Shea exhibit any merits yet. The newer yellows are represented by

PHŒBUS, one of the grandest of *Chrysanthemums*. The blooms are large, full, and deep, with wide petals of extra substance and richness. The colour is pure chrome-yellow, and the growth all that can be desired.

AMIRAL AVELLAN is a magnificent bloom with somewhat pointed florets. It is a huge, full massive flower, with a deep yellow shade of especial richness. A dwarf, easily grown kind.

PALLANZA.—From the first I thought much of this variety; and although the flowers I had subsequently seen appeared too small to suit the tastes of exhibitors, my early opinion is confirmed by the splendid blooms at Trent Park. They are of extra depth, full, and exceedingly rich. The colour is a deeper shade than that of *Sunflower*, and with that exception much like it in its best form. Little more need be said to commend it.

M. PANKOUCKE is a true Japanese, full, deep, and of curling formation; an especially fine show flower of M. Calvat's raising.

THOMAS WILKINS is a very fine large *Chrysanthemum*, and on that account will be popular, but personally I do not like to compare it with the few yellows I have already named. The formation is excellent, but the colour somewhat dull. A yellow that has failed to maintain its promise in this collection is *Duchess of York*.

The more striking among dark shades and other colours were—

M. GEORGES BRON.—A splendid dark crimson flower. The florets reflex, and thus show the dark shade which is welcome among so many light colours. This is a fine addition.

M. CH. MOLIN is a bronzy yellow, of great beauty. It has flat florets, and the blooms, although not of extra size, are full, deep and striking. The growth is excellent in this case.

MRS. W. H. LEES ought, perhaps, to have been included among the whites, but there is just a shade of pink in the lower portion to prevent it.

DEUIL DE JULES FERRY is scarcely open, but it promises to be an acquisition among dark-coloured flowers.

MEPHISTO is a huge bloom, of a reddish buff shade. There does not, however, seem to be much character in the formation, but the growth is extra dwarf. M. R. Ballantine, Directeur Tissierand, and Reine d'Angleterre also promise well. These are not yet open. Among the older sorts, E. Molyneux, Col. W. B. Smith, Viviani Morel, Mlle. Thérèse Rey, and many other noted Japanese

sorts are in magnificent form. The chief incurved flower of recent date is undoubtedly

GLOBE D'OR, one of the very best of that class ever seen. I should say the blooms measure nearly 6 inches by 5 inches, and have a perfectly finished appearance. The colour is buff-yellow. This sort is highly thought of by Mr. Lee.

J. AGATE.—This is a magnificent spotless white of very fine incurved shape. It is as large as the finest Empress of India—something that should recommend it.

ROBERT PETFIELD is a very fine pink flower, large, full, and deep. When the final touches are given to the specimens at Trent Park they will be among the best of the incurved blooms. Wm. Tunnington is promising, so also is Mrs. R. C. Kingston, but absolute failures are John Fulford, Owen's Crimson, Chas. H. Curtis, and others. I may, however, refer to these when I have seen them in other collections, for it is advisable not to condemn a variety unless seen in indifferent form everywhere. H. S.

#### CHRYSANTHEMUMS AT CAMBERWELL.

THERE are many difficulties in connection with growing the Chrysanthemum in close proximity to the heart of the great metropolis, but Mr. Norman Davis, of the Lilford Road Nurseries, always seems to overcome them. For some years past, probably fourteen or fifteen, the Lilford Road collection has always ranked as one of the leading trade displays, and has been a popular place of public resort during the autumn season. Mr. Davis has several glass structures full of plants in full bloom, but the chief interest must, of course, be centred in the large show house, so well known to all amateurs and visitors to Camberwell.

All the leading novelties of the past few years are to be found at Camberwell, whether they be of Continental or of American origin. Among Japanese, which, of course, are greatly in the majority, we noticed a thoroughly representative collection of Ernest Calvat's novelties, such as Dr. Allard, a Japanese incurved, a deep golden yellow, lined chestnut-red inside; Vice-President Calvat, a highly-coloured, mop-like flower, of crimson and gold; Mme. Carnot, a grand white Japanese, introduced two seasons ago; M. Gruyer, rather broad florets, curly at the tips, colour rosy mauve, tinted yellow in the centre. President Borel, now well known, is also in fine form. M. Pankoucke, a rich yellow Japanese, certificated by the N.C.S. last season, is also likely to maintain its reputation. Souvenir de petite Amie, white and dwarf, is also in good form. Another grand white, Mlle. Thérèse Rey, too well known to require description here, is still regarded by Mr. Davis as the best of its colour. M. Ch. Molin, Louise, and one or two others from the same source are also entitled to a special word of mention. Other varieties of E. Calvat's are Reine d'Angleterre, certificated last season, rather a loosely-built flower, somewhat like a rosy purple Condor, and Amiral Avellan, only sent out this spring, a very rich shade of golden yellow and a most promising variety, as it is good wherever we have seen it.

The other Continental growers are represented by Globe d'Or, a finely-incurved variety, rather large in size and of a pure golden yellow-tinted bronze; by Comite Lurani, a charming Japanese, figured in THE GARDEN of September 29, 1894, and of a beautiful shade of rosy pink on a white ground; M. Joanny Molin, brilliant crimson, but rather small for a Japanese; and Junon, a fine Anemone, of pale lilac, with fine ray florets. Mme. Paul Lacroix, pale sulphur-white, rather large, and Hamlet, introduced many years ago, but still a grand shade of salmon-carmine, with a golden reverse, maintain the reputation of growers like M. Simon Délaux and M. L. Lacroix. Vivand Morel, raised by the latter-named gentleman, is always good, and even in America regarded as one of the best. Th. Denis, Mlle. Mélanie Fabre, Le Deuil (a well-known Anemone), Descartes (also an Anemone, and one of the finest tones of colour in the section—rich velvety, vinous

crimson, with a high centre speckled gold), and M. R. Babuant, an incurved now in general cultivation, all come from the other side of the Channel.

American novelties of course at once suggest the name of Philadelphia, the much-vaunted Japanese incurved, which received a silver-gilt medal at the Royal Aquarium last November, after being sent 3000 miles across the Atlantic. As growing at Camberwell and at other places it cannot be fairly described as a white; the colour is really a pale sulphur-yellow. Mrs. R. C. Kingston, a variety raised by Mr. Surman, of Philadelphia, is a fine type of the true incurved, and was certificated as such last year. This seems to maintain its form, a rarity with most of the best American kinds; the colour is lilac-pink, and the blooms are something between a Princess of Wales and a Princess of Teck. G. W. Childs, a rich velvety crimson, is exceptionally fine; Mrs. E. G. Hill, introduced last year, is early, and a good pale pink Japanese very round in form. Niveum, a fine white Japanese, also keeps its good name. A new variety, Major Bonaffon, is not at the time of writing sufficiently expanded to say whether it will be of the true incurved or the Japanese incurved, but the colour is pure and clear, a decided yellow. J. H. Runci-man has broad florets notched at the tips, and is a variety of the Japanese section, colour rich golden yellow.

Passing on to home-raised and other varieties, we found H. Shoemith, a Japanese with long drooping florets, colour pale lemon-tinted canary, in good form. Pallanza, a grand golden yellow Japanese, and William Seward, very dark crimson, were also much in evidence. Charles Davis, the rosy-bronze sport from Vivand Morel, still remains as good as ever. Lady Byron, a new white Japanese recently certificated, but not yet in commerce, is also considered to be a most promising novelty. Pride of Madford, a rich shade of rosy-amaranth, is a seedling raised in Australia. Mrs. E. S. Trafford, a rosy-bronze sport from Wm. Tricker, is fairly well known, and William Bolia, rosy-purple amaranth, is a bright-looking Japanese kind.

In the small house adjoining Mr. Davis has an interesting collection of all the old Anemone and reflexed sorts, which he has collected for purpose of identification. There are about a hundred varieties of Anemones and thirty varieties of reflexed, many of which present-day cultivators would hardly know.

There were still a few early-flowering varieties at the time of our visit; one, Commt. Schneider, a small reflexed Japanese not unlike old Progne, was violet scented. There was a large number of the white and yellow forms of Lady Selborne, Rycroft Glory, Lady Fitzwygram, Chev. Ange Bandiera, Saml. Barlow, Arthur Crépey, M. Louis Lionnet, Mme. Hy. Devered, and others of the early group.

**Chrysanthemums in fruit houses.**—I have always been opposed to putting plants into fruit houses even if occupying only side shelves or stages, but what is to be said of the present-day system of blocking up Peach houses and vineries with Chrysanthemums in October? At this date Peach trees, especially in late houses, have still much of their foliage left on them, and the roots need all the air and sun possible, as un-matured roots mean unripened wood and badly developed fruit and wood-buds. Moreover, the best and most fibrous portion of the roots which lies nearest the surface of the border is kept in a saturated condition by the repeated watering of the Chrysanthemums, the case being rendered much worse when the pots are stood on the bare border and not on bricks or trellises. Depend upon it, the deterioration of many fine healthy Peach and Nectarine trees is due entirely to crowding the house with Chrysanthemums. Many gardeners also lacking space are compelled to use their vineries for the same purpose, closing the ventilators and even employing fire-heat in order to shield the foliage from frost or keep the blooms from damping, and this, too, at a time when the

utmost coolness and even a few degrees of frost would be a boon to the Vines. Of course, the plants must be accommodated somewhere, but while congratulating all those who are fortunate enough to possess a large conservatory, carriage court, or some such structure capable of holding all their stock, I would urge upon others lacking this convenience the necessity of storing as many of their plants as possible in houses not containing fruit trees, and as few as possible in vineries and Peach houses.—J. C.

**Fragrant Chrysanthemums.**—A few years ago there was some little interest in these, and the names of several varieties were recorded in THE GARDEN as possessing the peculiarity of perfume. Commandant Schneider, a small Japanese of reflexed form, colour purple-amaranth, was pointed out to me the other day by Mr. Davis, of Camberwell, and the perfume was undoubtedly that of Violets. More recently at Swanley, Messrs. Cannell's foreman showed me a variety called Striped Odorata, a small blush-coloured Japanese with a stripe of yellow down the middle of each floret, which smelt sweetly, although it was difficult to say what its scent was like. It seems that hot, dry weather is favourable for the detection of sweet-smelling Chrysanthemums, as both growers pointed out that it was always more noticeable under such circumstances.—CHRY-SANTH.

#### CHRYSANTHEMUMS AT LEWISHAM.

MANY growers and admirers of the popular autumn flower will remember Mr. H. J. Jones settling down at the Rycroft Nursery, Hither Green, Lewisham, some five years ago, and must be astonished at the rapid, but well-deserved success that has attended him as a raiser, grower, and importer of new Chrysanthemums. As an exhibitor at some of the large shows his departure from beaten tracks, but particularly the artistic displays of cut blooms in vases, which he was the first to bring into prominence, excited great attention from many who had become tired of the ordinary crowded groups usually met with, and called forth much praise from those who could properly appreciate the innovation.

Our visit to Rycroft Nursery was made this year towards the close of October, and although we expected much we were by no means disappointed, for the collection was in a very advanced state, there being but few flowers undeveloped. There are several large greenhouses in which Chrysanthemums are housed, and the Rycroft collection contains a large percentage this season of finely grown varieties of recognised merit besides all the novelties from the home and foreign raisers. It is probably the largest and most representative collection of new Chrysanthemums in the United Kingdom, and bears evidence of close attention and continuous labour in the admirable way in which the plants display their blooms.

This year an alteration has been made in grouping the Chrysanthemums in the large show greenhouse. A bank of plants runs down the middle of the house the whole way, a narrow bank being placed down the sides, leaving a sinuous, winding path between. It seems to be an improvement on the plan adopted in previous years, when there was only one path down the middle and a group of plants on each side. On entering, the visitor is struck with the brightness and clearness of colour visible and the tasteful method of arranging the colours. There are some splendid examples of cultural skill in many cases, the flowers of William Seward being the finest we have seen. There are large numbers of some of the old established favourite varieties such as Charles Davis, Col. Smith, Mrs. E. S. Trafford, but newer ones like Mrs. E. G. Whittle, Phœbus, Pallanza, Miss Ethel Addison, M. Ch. Molin, C. H. Curtis, D. B. Crane, Descartes, A. H. Fewkes, &c., can be found in quantity.

Dealing first with Continental novelties, the seedlings of that eminently successful grower, M. Ernest Calvat, claim the premier position. M. Ch.

Molin, a Japanese, rich yellow and bronze, is very attractive; President Borel, another well-known kind, needs no description: Mme. Ad. Chatin, a fine white Japanese, is in good form, as is also Deuil de Jules Ferry, a rosy amaranth and silvery Japanese of a very rich tone. Amiral Avellan is a very fine golden yellow Japanese; Souvenir de Petite Amie, white, and Louise, a massive incurving Japanese, recently seen at the shows in excellent form, maintain the opinion formed of them several years ago when first introduced and certificated. Mme. M. Ricoud is useful for amateurs, as it comes easy; it is a Japanese of globular form, colour pretty shade of rosy pink tipped white. L'Aigle des Alpes is very distinct; it has rather broad florets, incurving at the tips, colour carmine-crimson with golden reverse. M. J. Ginot is a Japanese, colour purplish amaranth, silvery white reverse. Mlle. Thérèse Rey, the finest white Japanese in existence, both here and in New Zealand, also substantiates its claim to superiority. Commandant Blusset, rich purple-amaranth, is also a Japanese of striking colour and effect. M. J. Lallemand, although a novelty of 1895, is too long in the floret and too loose even for a Japanese, and Reine d'Angleterre, very large, but loose, is a white Japanese, suffused purple. Very bright in its crimson and gold is M. B. Giroud, a deep, round-built flower of good Japanese form. Noces d'Or is of a fine clear shade of golden yellow, an incurving Japanese; Mme. Carnot, a large white Japanese; and President Carnot, crimson-carmine and golden reverse, are both in good form. Boule d'Or seems likely to be one of the greatest favourites with those who like the large, solid incurved Japanese, the colour, a golden amber, being very distinct. President Armand, Directeur Tisserand and many others are equally meritorious.

Other French growers, such as M. Lacroix and M. Hoste, are also represented, and several others whose names are not so familiar to English growers. Phœbus, a new yellow Japanese of a rich golden shade, and Linée, a Japanese incurved, chestnut and buff, both come from the former raiser. Mme. Paul Lacroix is another, a Japanese of pale sulphur-yellow passing to primrose. M. Ch. Delahousse is very distinct, a fine velvety purple-amaranth, silvery pink reverse, a Japanese. La Garonne, a pretty Japanese of medium size, suffused rosy pink, centre tinted yellow; Sirène, a Japanese reflexing bloom, pale blush, and Jean Bart, a Japanese, colour terra-cotta with golden reverse, a warm shade of colour, are all worthy of a note. Then Tendresse, a Japanese, rather loose in build, but of a delicate blush, tinted yellow, Globe d'Or, one of the few real incurved kinds from France, a fine form, colour pure golden yellow, and others such as Duchesse de Grammont, Surprise, M. Aug. Lacvievier, Phryné, Guirlande, C. Darville, Mme. Rozain, Le Fringant, M. Catros Geraud, &c., arrest attention.

American seedlings are not quite so numerous or so fine as we might have expected, excepting here and there. Home-raised seedlings and one or two Australian novelties help to swell the collection, and it is pleasing to record that some of the English amateurs, like Mr. Shea and Mr. Brisbane-Ironside, are still busy at the work, and, knowing the requirements of the English exhibitor, are less likely to work haphazard than some of the foreigners seem to do. Mrs. C. E. Shea, the large white Japanese introduced this spring, is pale sulphur in colour, but a later bud is suggested where greater purity of tint is required. Miss Ethel Addison, a large incurved Japanese, amaranth and silver; Mutual Friend, a large white American Japanese; and Pallanza, rich golden yellow, are all faultless both in size and colour. King of the Chrysanthemums is striking; it is a golden buff Japanese. Miss Clara Walker, a large pure white Japanese, is remarkable for its length of floret. A. H. Fewkes, Japanese incurved, is rich deep yellow, and Duchess of Wellington is of the same type and colour. Col. W. B. Smith is well known; so, too, are Mme. Cambon, Mrs. E. G. Hill, and Col. Chase. Philadelphia is disappointing, the colour is far from the pure

white which we saw last year when it was sent over from America. Queen of the Buffs, Lady Playfair, Mrs. Geo. J. Iles, Mrs. D. Airdrie, Pearl Beauty, and many others must be passed over owing to want of space.

Incurved varieties are well represented, D. B. Crane, a richly coloured, well-formed variety, being one of the newest. Chas. H. Curtis is large, pure yellow in colour, and has very sharply pointed florets. Baron Hirsch, fine in build, rich golden chestnut, is also good. Mme. Darrier, nankeen-yellow; Globe d'Or, golden yellow; and Mr. James Murray, bright rosy pink and new, are well represented. Other varieties, viz., Refulgens, Mme. F. Mistral, Brookleigh Gem, Jeanne d'Arc, J. Agate, Golden Empress of India prove that Mr. Jones takes an interest in the older known section, and does not confine his efforts to the more popular race of Japanese exclusively. There are some examples of hairy varieties, many of quite modern origin. Vaucanson, figured and described in THE GARDEN last season, is the first to be observed. A new one called Perle d'Or, a clear shade of pale yellow, but rather thin in the petal, is only slightly hairy. Papa Bertin, also new, is peculiar in form, having long tubular florets, very curly at the tips, colour silvery pink. Hairy Wonder, reddish bronze, is well known, and a very fine bloom of the famous white Mrs. Alpheus Hardy, the forerunner of the section, is also well open. Prima Donna and King of the Hirsutes are not novelties of the year, but P. Marieton is. It is large and solid, a Japanese golden bronze, shaded yellow. Enfant des deux Mondes is best known as White Louis Boehmer, and the last of this race to be mentioned is Abbé Pierre Arthur.

Altogether the Ryecroft collection may be regarded this year as one of the best, and the task of going round the large house occupied the whole of the afternoon. Visitors during the next fortnight will see much more to interest them than can be indicated in an article like this, and the collection will well repay a visit even late in the month, unless the metropolitan and provincial shows make a heavy demand upon Mr. Jones' resources.

**Chrysanthemum La Vierge.**—Although this is a comparatively old variety, there are few, if any, of the newer kinds to beat it. The flowers are of the purest white, without the least tinge of pink, and are far superior to those of Mme. Desgrange in that respect. It is a midseason variety. I have at the present time some plants in 7-inch pots that are not more than 18 inches high, each one having three or four stems with large clusters of snow-white flowers on each. The reader will be able to judge how valuable such a variety is for all the purposes of ordinary decoration, as plants of the height I have mentioned can be obtained by once stopping the principal growth.—J. C. CLARKE.

**Chrysanthemum W. H. Lincoln Improved.**—This fine yellow kind promises very well. It is of medium height, of vigorous habit, and is likely to become one of the most popular of market kinds for semi early work. In the growing season, by reason of its free rooting, it requires much greater supplies of moisture than many and must be carefully noted in this respect. The flowers are of a good deep yellow and of the Japanese incurved type, the same as the seed parent. Like W. H. Lincoln, the improved kind is very free, giving fair-sized flowers on good stiff stems from the terminal buds. It is also a capital variety for crown buds. There is room for both kinds, as the type flowers somewhat later than the improved form.

**New Chrysanthemums.**—Not only is the attendance of bona-fide gardeners and amateur cultivators of the Chrysanthemum at the National Society's November exhibition without doubt the greatest of its kind in the kingdom, but the wish for anything new shows how deep is the interest taken in the new flowers, of which there are always so many. Some of the new varieties of last year have not proved to be very satisfactory,

and it is not too much to ask that a little more care should be exercised in the ordering of novelties so that disappointments may be averted. One specially over-praised flower proved this season, though largely bloomed in the country, to have been almost worthless, and should of itself cause those who can often ill-afford large sums for novelties to exercise more patience ere they haste to buy. Another variety, for which the outrageous price of one guinea per plant was paid, is far less worthy of notice than are many sold at 2s. or 3s. each. It is a pity the National Society has not its own means of testing all novelties by good growth before giving certificates of merit. So far the best tests are to be found in the collections of our leading trade growers, who invariably grow all their plants so well, and where there is always the greatest facility for comparing new kinds with old ones. That there have been many remarkably fine flowers shown this year which are full of promise there can be no doubt, but were it the rule to grant certificates only when grown and shown two years in this country, possibly fewer certificates would be awarded, as it is most noticeable how many thus honoured fail to take a prominent position later. Nothing can be more unfortunate than that to satisfy pure trade exigencies the impress of a certificate of merit should be given to what is after all under wider cultivation a worthless variety.—A. D.

#### SOME LARGE JAPANESE CHRYSANTHEMUMS.

WHATEVER the demerits of size may be in a Chrysanthemum, one thing is certain—that the visitors do not disregard it. During the past few weeks I have met with several examples of recent introduction in which size is a leading feature, and may mention as the most notable in this respect—

**PRIDE OF MADFORD,** a large Japanese incurved, of Australian origin, very globular in form and substantial. The florets are broad and deeply grooved, colour rich rosy amaranth, reverse silvery, streaked amaranth.

**AUSTRALIE** is also from the same part of the world and of the same type, but the colour is more dull, a rosy amaranth, with a leaden-pink reverse. The florets are broad, pointed at the tips, and veined on the outer surface.

**AUSTRALIAN GOLD.**—Although a French-raised variety (one of Calvat's), it is a curious coincidence that its name might possibly suggest a colonial origin. This is a pure Japanese of immense size, a very full double flower; florets rather narrow, colour rich canary-yellow, tinted lemon in the centre, reverse silvery yellow.

**MUTUAL FRIEND.**—An American variety, very large, the long florets being deeply grooved and curly; colour wax-like white.

**RE D'ITALIA.**—One of Mr. Ironside's seedlings, a Japanese belonging to the spidery or octopus type. The florets are loosely arranged, of immense length, and, being tubular, do not show the inside colour, which is reddish chestnut except at the open tips. The reverse is straw yellow.

**EDITH TABOR.**—Probably the most beautiful of the set. It is a pure Japanese, of very fine form, with long drooping florets, curly at the tips; colour clear canary-yellow, shaded lemon.

CHRYSANTH.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Phœbus.**—This handsome flower has no equal among early kinds at present, especially in point of colour. This is a deep shining gold, exceedingly rich, the florets drooping in the most graceful fashion. It comes into bloom at the end of October and, disbudded, makes a large handsome flower. It grows rather too tall.

**Chrysanthemum Mrs. Charles Blick.**—At a recent meeting of the R.H.S. at the Drill Hall a fine group of this grand white variety was exhibited. The plants, each from 2 feet to 2½ feet high, were in 6-inch pots and carried a single flower of large size and great purity. Such examples would no doubt prove valuable for decoration.

## HARDWICKE GRANGE, SHREWSBURY.

HARDWICKE—now the seat of Mr. J. J. Bibby—is a simple old English house, standing in the midst of a spacious park and gardens in some of the finest country that surrounds the ancient town of Shrewsbury. It was formerly the home of Lord Hill, of the Peninsular War fame. He, after the termination of that long campaign, settled down here and took an active interest in his garden, a number of the trees that now adorn the grounds having been planted under his direction. The situation of Hardwicke is rather flat, and its own well-wooded surroundings shut out most of the hilly scenery of the district; but this is no loss when one meets at every turn trees, shrubs and flowers of interest and beauty, maintaining a fresh, but changing, picture throughout the year of the best flowers of the time. This is the kind of garden that literally surrounds Hardwicke. The flowers are not all gathered together into one spot and set down in an imposing array, but one finds them everywhere growing in situations that they fittingly adorn and under suitable conditions.

The engraving we here give of Hardwicke shows its carriage front or park view. The

lawn and a few good specimen conifers, such as *Abies canadensis*, *A. cephalonica*, and the Silver Fir. A tree of *A. nobilis* shows well the absurdity of grafting conifers. It is grafted on the Silver Fir, and, although an old plant and healthy, it is only 30 feet high and always makes a stunted, distorted growth. A very fine Beech tree with a large, clean bole and an enormous head of branches stands near. Among a group of *Rhododendrons*, *Azaleas*, and other flowering shrubs we recognised the lovely and hardy *Arundinaria nitida*, whose origin and name have only lately been cleared up. The plant in question was purchased under another name, and although Bamboos were hard hit by the frost at Hardwicke, this plant came out uninjured, and thus from another district we have proof of its exceeding hardiness, whilst it is second to none in gracefulness, and altogether unique in the pretty colour of its young canes. From this part of the garden a walk leading to other parts of the grounds is margined by a line of fine Cob Nut trees that were planted by the late Lord Hill. They are now of large size and stand upon the turf, whilst behind them is a border of hardy flowers, in which *Paeonies* are most prominent, whilst it was edged beautifully

and flowering shrubs and hardy flowers, with Grass walks giving access to the respective groups. In a little wood, yet still quite near the house, is another delightful bit of gardening only as yet in its infancy, rich in promise of good things to follow, but even when we saw it not without features of beauty, different from any others in the place. Once a marl pit, it became afterwards a garden rubbish receptacle, but now Mr. Taylor has made it one of the beauty spots of the place and a home for much fine vegetation that other parts of the garden would not grow. A tiny stream of water winding through the bottom of this now picturesque hollow provides a congenial home for moisture-loving plants, and amongst those now thriving there are *Iris Kämpferi* in great luxuriance, Royal and other hardy Ferns growing tall and spreading into graceful groups, *Spiraea Aruncus* rivaling the shrubby kinds in size and showy display, with *S. palmata* and its white form less in stature, but spreading and blooming, as does the Meadow Sweet in the rich hollows of our woods. Here, too, a goodly number of Bamboos had been fairly established, but last winter injured them very much, some of them being cut down quite to the ground line. A walk winds by an easy way along the undulating slopes of this old pit, and at every few yards shows a different blending of suitable plants, flowering shrubs and hardy flowers always the most prominent. Hardy *Cyclamens* we were pleased to see in abundant blossom.

In and about the kitchen garden quarters the best hardy flowers of every season were constantly seen. Good mixed borders that are gay nine months of the year, and borders or groups of special families that space will not permit of our doing justice to were seen and admired. Certainly from Snowdrop time till the last of the hardy Sunflowers fade, outdoor flowers are one of the chief charms of this old garden. In the vegetable quarters, too, there is abundant evidence of the same good cultivation, and fruit likewise is well grown. Peaches do well outside in the district and the wall devoted to them here is perfect. Under glass, too, are grown admirable Grapes, Peaches, Melons, Cucumbers and Tomatoes. Orchids, too, have a share of attention, and the little range devoted to them in its cool, intermediate and warm compartments is filled with a collection representative of all that is most beautiful and useful in these flowers. Carnations are in request the whole year round, and a well-constructed range of Mr. Taylor's own designing is devoted to these in winter. These houses have a central pathway with front staging and a three-tier staging at the back, every portion of the staging being within easy reach of the pathway of the house, so that the plants can be easily and quickly attended to. *Chrysanthemums* likewise are largely grown. The garden at Hardwicke is just the kind of garden one longs to see more often.

**Eradicating weeds.**—On large estates, and especially in wet seasons, weeds are a source of much annoyance to those responsible for keeping walks and drives in good condition. Hoeing and raking incur a deal of labour, and are after all very unsatisfactory. With so many patent liquid weed destroyers in the market, however, there need be no difficulty in keeping the walks clean, and that, too, at a nominal cost. On riding through the extensive deer park of a Norfolk nobleman and remarking how clean and bright the drives were, I was informed that one of the popular weed destroyers was applied in liquid form once in eighteen months, the result being that for that period not a weed was visible. The

Hardwicke Grange, Shrewsbury. Engraved for THE GARDEN from a photograph by Mr. J. Laing, Shrewsbury.

drive that leads up to it traverses a park that has many fine specimens of native trees and grand groups of the common Holly, certainly one of the noblest of evergreens, and when at its best unequalled by any exotic evergreen that will grow in this country. It is well cared for here, as in the spring previous to our visit some of the groups had been thinned by transplanting to make fresh groups elsewhere, and with prospects of success, judging from the appearance of the trees when we saw them. Just before reaching the house a little lake comes into the foreground, as shown in the picture—a future home for the new series of hardy Water Lilies—and the garden itself is entered. The luxuriant growth of Holly is again manifested by a splendid piece of a silver variegated variety, well shown in the picture, hiding a part of the house. On the left is a little garden devoted chiefly to summer flowers. At the time of our visit *Antirrhinums* were a bright feature here, fine, free, handsome self kinds, yellow, white, and crimson being massed in beds with other plants. Such forms as these are distinctly good, and much to be preferred to the pigmy strains that have been brought out of late years. On the opposite side of the house to the carriage front there is a fine expanse of

with a broad margin of *Viola cornuta*. On the opposite side of the path, and also with a grassy foreground, was one of the brightest flower borders at the time of our visit. It was planted with the Prairie Sunflower (*Helianthus rigidus*) and the white Japan Anemone, with Carnations in front, the number and great variety of these latter showing that these flowers are popular here and well grown also. The best flowers were past when we saw them, but we noted a few, and these some of the newest kinds, still good, especially Hayes' Scarlet, The Pasha, Mephisto, Mrs. Audrey Campbell, Ladas, Pride of the Garden, Duchess of Fife, and others. A number of French varieties, both selfs and fancies, were under trial, and in regard to these Mr. Taylor had much to say in praise of their fine constitution, as proved by their vigorous growth and long-lasting season of bloom. Here, as we have often seen before, it was possible at a glance to point out where a group of French varieties ceased and another of English kinds commenced, although the plantations were side by side under like conditions of soil and treatment. A pretty corner is found at the end of this walk where the soil has been formed into gentle natural mounds and planted with choice evergreen

use of these weed-killers is a great gain from a financial point of view, as a long distance of road can be traversed by a couple of men in a single day, and the many weeks which it once took to hoe and rake can be spent in something much more profitable. In small gardens and pleasure grounds salt answers very well, as if it is applied during settled weather, it generally does its work well. Still there is a certain amount of risk in using it.—J. C.

## KITCHEN GARDEN.

### LARGE CARROTS.

It may be assumed that Carrots are exceptionally large this year. No doubt these considerable dimensions are largely due to the season, but they are also to some extent due to the practice of saving seed from large roots, so that size is in danger of becoming more and more developed. That may be thought a gain, and perhaps from the cattle feeding point of view is so. For our own tables, however, we have need of pleasant eating quality, soft texture, sweet and flavoured flesh, and these are elements in Carrots not usually associated with very large roots. How very much the New Intermediate type, the St. Valery of the French, has increased in size of late, so that roots now rival the Parsnip in stoutness and length. Surely it cannot be admitted that for ordinary consumption such sorts are desirable. In the collection of vegetables that Mr. Empson, of Amptill, staged at the Drill Hall on the 29th ult. were wonderful specimens of various Carrots, and as handsome and bright as if modelled of wax, yet all their beauty could not condone their exceeding bigness. But with these was staged also a sample either of the Scarlet Champion or a variety much like it, the roots about 7 inches long and of corresponding diameter that were not merely perfect as edible Carrots, but as beautiful as the most exacting of judges could desire. These were ideal Carrots for ordinary consumption, large enough for anything, and should have been of soft delicious flesh when properly cooked. It is impossible to cook the large roots now so plentiful when whole. They have to be cut into several portions first, and then when boiled they are quite flavourless. Why should we for the sake of securing roots of the inordinate dimensions deprive ourselves of the pleasure to be derived from partaking of what is in small Carrots soft, succulent, pleasant flavoured food? Cannot this tendency to become unduly big be corrected by sowing seed less early? Do we not give the roots too long a season in the ground? What Carrots now that have been raised from spring sowings can compete in table quality with those yet young and obtained from a July sowing? Are we not in our craving after bigness, the product, no doubt, of exhibiting, in danger of dethroning the Carrot from its former popular position as an edible nutritious root? It is often pleaded that judges of vegetables should condemn this tendency to set up large roots. The common difficulty experienced is that let judges have ever so much fondness for high table quality on such occasions, yet where all the roots alike are large they have no option. We shall never get satisfactory judging of vegetables at shows until the dinner table standard is taken. It is, no doubt, fair to say that at exhibitions what is to be looked for is not table quality at all, but rather evidence of what respective products can evolve in both dimensions and beauty. That may be from one point of view good

reasoning, but it can hardly have the same weight as the stronger argument, that as the primary reason why we grow vegetables is that they may make us the most acceptable and healthful form of food, so should these examples seen at exhibitions be estimated on the same principle. No doubt modern Carrots show a great advance on older varieties, but there is danger such advance may be discounted by the production of such needlessly large roots. A. D.

**Snow's Winter Broccoli.**—In THE GARDEN (p. 326) "W. S." spoke of the disappointment he had of late years experienced with this old-fashioned Broccoli, it having headed in most unsatisfactorily. I may say that my experience with it is much the same as his; indeed, on that account I have this year grown none of it. The last planting I made not only produced inferior heads, but these came at widely different periods, some appearing at mid-winter—its proper date—and others in spring. The fact is there has been such a universal demand for these good old strains of Broccoli and Cauliflower, that, as "W. S." says, they have degenerated. This is why I have given up growing Early London Cauliflower. If "W. S." has not yet tried Backhouse's Winter White, I would advise him to do so, as I find it a most reliable Broccoli for December cutting and of snowy whiteness and fine mild flavour. It is very distinct in habit of growth and resists a good amount of frost.—J. C.

**The Carter Spinach.**—Reference was made in THE GARDEN in the spring as to the value of this Spinach for early supplies, and also as to the size and substance of the leaves. It may be of interest to state that it is equally valuable for autumn supplies. Sown at the end of July with two other varieties under similar conditions, it far surpasses both in productiveness, size of leaf and crispness, a large basketful being picked daily from a small plot of ground. In the future I hope to grow considerably more of this variety, to the exclusion of others.—W. G. C.

**Turnips Chirk Castle Black Stone and Orange Jelly.**—I question if there are two better varieties of Turnips than the above for winter work, but the former is now seldom met with. Where Turnip-tops are required in the spring Chirk Castle is unrivalled, as it will pass through the most severe winter uninjured and provide a long succession of tender tops. Not only so, but occasionally the Turnips stored for winter use have kept badly, decaying or becoming woolly, and I have been obliged to fall back upon Chirk Castle standing outside; the small dark bulbs always find favour. Orange Jelly is a larger and handsomer Turnip, ranking next to Chirk Castle as a keeper, and of nice colour and good quality when cooked. I find this and other varieties keep fresh and plump much better if clamped the same as Potatoes, as they do not become so dry and flavourless as in the root sheds. To save labour the bulbs may be clamped on the ground on which they grew, putting a few bushels in a clump, so that if the weather is sharp a whole heap can be removed into the root shed and consumed as required.—W. G. C.

**Manuring Asparagus beds.**—Opinions differ as to the value of manuring Asparagus beds which are in good bearing condition. I think manuring at this season in many cases does more harm than good, as a mass of manure causes many roots to decay, and those which do survive are weak and only throw up poor grass. I would much rather rely upon liberal supplies of food through the growing season than give manure at this date, as at that time the roots can more readily absorb the food given. By feeding from April to August the crowns are built up for the next season's supply of grass. The roots of Asparagus are always active, but much less so in winter than at any other season, and they obtain quite sufficient nutriment from the soil to support them. If heavily covered with manure, growth

is checked, and the roots have to fight hard for existence when they are none too strong and are deeply buried. Again, the same objections hold good in the case of applying salt in the late autumn: it is equally as injurious as giving manures; indeed, more so, the soil being made wet and cold. I like to apply salt in showery weather from May to August, and at intervals. If such aids as fish manure can be given also, they cause a quick root action and the grass is of superior flavour. Fish manure alone is excellent for surface dressings. Guano also is a grand fertiliser, used as advised for fish manure. Salt given now causes late spring growth even on light soils, and, though at times advised, is the cause of beds failing. Of late, more Asparagus has been grown on the flat with a wider space between the plants. This is as it should be. The old plan of growing in beds, often in rows not more than 12 inches apart, was bad, the plants making a free top growth could not develop, and the result was poor crops. There is no loss by giving ample space, as a row of a low-growing crop can be put out between the plants. I do not like the raised bed system, especially on light land, as the beds are too much drained. With ample space—at least 3 feet between the rows (more is better) and plenty of space between the plants—there will be better results. Few vegetables give a better return than Asparagus if well supplied with liquid manure during growth. I would much rather rely upon liquid food than manure at this date.—G. W.

**Saving Asparagus seed.**—I do not think we pay sufficient attention to this matter, and by haphazard seed-saving get poor plants which never make good strong growth. I am aware there are several varieties of this vegetable, but so far, out of some six kinds sown purposely for trial, I can find but two varieties, and these do not differ much from older kinds. I am aware much of the difficulty in growing this vegetable is owing to the way in which it is cultivated. Careful seed selection, getting the seed from the best plants, is an important matter. It will be found that many of the seeds are produced on weak spray. The seeds should be secured from the best growths, not from crowded beds. Seeds obtained thus are more vigorous and need to be sown thinly.—S. H.

**Late Savoys.**—I do not think the above vegetable is so valuable as towards the close of the year. If sown and planted early and on warm borders, Savoys soon get coarse, having white hearts, which burst or split at the first severe frost. To get late Savoys, it is necessary to sow late, early in May being quite soon enough. I think early Savoys not worth cooking, as they are so strongly flavoured. It is surprising what severe weather these plants will endure if the heads are green and the plants close to the soil, in an open position for the first supplies, and for the latest on an east or north border. Of varieties we have large, medium and small. The large Drumhead is one of our most useful winter vegetables when grown late as advised.—G. WYTHES.

**Renown Potato.**—Will "J. C." kindly state which of the two round white varieties in cultivation under the name of Renown he refers to at page 343? One was put into commerce by Mr. R. Dean, Ealing, and the other by Messrs. Webb and Sons, Wordsley. Fortunately, it is rare that duplicate names are given to Potatoes, although so many new ones are from time to time put into commerce. I have grown both these varieties during the past season and found both very good. It has been an admirable feature of all round sorts that they have preserved their form so admirably, whilst long-tubed varieties have grown out and become most ungainly. For market sale the round kinds have given a long way the most profitable samples.—A. D.

**Quality in Cabbage.**—There is no difficulty in having good Cabbages from September well into March if suitable varieties are grown—small kinds and those noted for quality in preference to those of large size. One of the best Cabbages I

have grown for autumn cutting, when flavour is considered, is Little Gem, a very small green, compact grower, cone shaped, and of delicious flavour. Favourite is somewhat similar, and though a trifle larger than Gem, is like it in quality and growth. Other good Cabbages for winter supplies—flavour being the principal point—are the St. John's Day and Christmas Drumhead. The older Winnigstadt is another valuable autumn Cabbage. I admit it is larger than the above varieties, but as regards quality it is one of the best of the larger sections, and valuable in late districts on cold heavy soils. The Rosette Colewort I have previously noted for early autumn supplies, and for use after Christmas the Hardy Green will not fail to give a full supply.—G. WYTHES.

**Quality in cooked Potatoes.**—Very great allowance will have to be made for the somewhat indifferent quality found in many Potatoes, but especially in the long or kidney section, resulting from the new late growth made after the heavy rains in August. I find that whilst good rounds

James's Keeping, brighter in colour and of perfect shape. There is but little core and the root is very sweet. The roots keep well, are fuller at the top than those of many kinds, and have a rounded, neater appearance.—G. W.

## ORCHARD AND FRUIT GARDEN.

### GRAPES IN PLANT HOUSES.

It is often said that it is not possible to grow good Grapes in a house kept filled with plants during the whole of the year, while some even go further and maintain that pot plants ought to be kept out of vineries altogether. That pot plants are very much in the way at times there is no disputing, and most of us would prefer to have a clear course from the time the Vines are in flower till the fruit is cut. Nor must we overlook the importance attached

fernerly, and at the other end is a plant stove. It is span-roofed, running from north to south on a steep bank, the floor being brought up to a level by means of extra high walls. The length is about 33 feet, width 12 feet, height of side walls and lights above ground-floor 6 feet, and the apex of roof 12 feet. There is a trellised pathway 3 feet wide, and on each side staging for pot plants. I give these details in order to show more plainly than does the accompanying reproduction from a photograph that it is not a great roomy house. Even the ventilation is not anything like what the expert Grape grower would expect to find, as there are only cap ventilators for the roof and not much side ventilation, the doorway leading out of the fernery being the most effective means of admitting fresh air in quantity. The border is inside and wholly above the ground-level. At the present time it is the full width of the house and about 9 feet in length. At first two

Vines were planted, one Foster's Seedling and the other Muscat of Alexandria, each occupying a corner of the house. The latter variety was naturally most valued by Mr. Baily, and as it grew away strongly and promised to do well in other ways, he decided to gradually fill the house with it. A young cane was conducted from it under the pathway and layered into the fresh compost placed in the hole previously cleared of the soil occupied by the roots of Foster's Seedling. Along the lower part of each roof there is now trained a main rod, other rods being taken up the roof at intervals of about 4 feet.

If I remember rightly, the Vine has been planted not less than eight years, and at the present time only covers about three parts of the roof, so that the progress has not been rapid, but then the crops have been decidedly heavier than are usually left on Vines of Muscat of Alexandria. This season twenty-one large bunches were left, all furnished with perfectly set berries, the average weight being at least 2½ lbs. each. At Trowbridge the bunches cut from it and shown were considered good enough for a first prize, as well as a special prize offered for the most meritorious exhibit in the fruit tent, and first prizes were also gained during August, fresh bunches being cut each time, at the Frome and Bath shows. In November another first was gained at Weston-super-Mare, and two of the very best bunches on the Vine have been saved for the Bristol Chrysanthemum show. That will give some idea of the quality of the Grapes.

The Vine starts naturally in March, gets but little, if any, syringing, as this would be prejudicial to the flowering plants, and only a warm greenhouse temperature is maintained throughout. There is no neglecting to thin out the breaks, which, in common with those of most Muscat Vines, are never very strong at the outset, and no delay in stopping laterals, though these are left to a considerable length in places, reducing the number of bunches to about thirty and never omitting the important detail of smartly tapping the bunches which show when they are in flower. The best-set bunches, whether large or only medium in size, are rightly selected, and every season it

*Grapes in a plant house. From a photograph by Miss M. Baily, Willow Vale, Frome.*

are alike throughout, and from sandy soil boiling admirably, the kidneys give flesh both fairly good and very soft or watery. That is the case with varieties that in ordinary seasons are excellent. Early Potatoes, where ripened off before the rains came, if not large are at least very good. Warmth is a most valuable agent in helping to create starch, or what we call mealiness in the tubers. There is much to be said also in relation to late-maturing varieties, that many of them become fit or ripe for eating only after having been stored several weeks.—A. D.

**Carrot New Red Intermediate.**—This new Carrot bids fair to oust such kinds as Altringham, Long Red Surrey and similar kinds, being more symmetrical and of a better colour. I do not care for large Carrots or those with great length of root, preferring those of an intermediate type. As far as quality is concerned there are none better than the stump-rooted section, but these are not always required. The above is a great advance on some of the older larger section, the roots being very solid and of excellent quality. This variety may be described as longer than

to giving the Vines a thorough rest, exposure to frosts doing good rather than harm, but we cannot run the water out of the hot-water pipes and boiler if there are tender plants in a vinery, and there is in such cases no possibility of giving the Vines a rest, unless, indeed, we resort to the old, but almost obsolete plan of turning the Vine rods out on to the roofs. When, therefore, cases are met with that quite upset all preconceived notions, these are worthy of recording. That really first-class Grapes can be grown in a house kept constantly filled with a variety of pot plants I have had abundant proof during the past six years, but this season the record, so to speak, has been broken.

In the gardens connected with Willow Vale, Frome, the residence of Mr. A. R. Baily, good Grapes are grown in the vinery proper and also in a Peach house, but the very best are cut from a Vine in a plant house kept as gay as possible all the year round. This compartment is approached through a small, but very pretty

has been found necessary to remove several extra large bunches imperfectly set. The thinning out of berries is done piecemeal and with good judgment; the greater portion saved have a good complement of stones, and attain a large size accordingly. In such a house and under such conditions it would not be surprising to find red spider prevalent, but neither this nor any other insects are allowed to gain a foothold, the sponge and soapy water proving the best remedy when applied in time. The border has been formed piecemeal, and to the latest addition of good brown fibrous loam, mortar rubbish, and half-inch bones may be attributed some of the success achieved this season. Nor must I omit mentioning that both Mr. Baily and his gardener, Mr. Carpenter, believe that Grape Vines rooting in inside borders should have abundance of water during the growing season, and the Vine under notice has plenty of water and liquid manure.

During the summer I have seen a *Stephanotis* flowering freely in one corner of the house, a *Bougainvillea* in the other flowering grandly, and a good crop of Tomatoes on the rest of the roof between them and the Vine. Underneath, all through the summer, there are invariably some Orchids in flower, as well as *Begonias*, zonal *Pelargoniums*, *Roses*, and *Carnations*, with *Caladiums*, *Coleuses*, *Cyperuses*, *Grasses*, and *Ferns*. Just now there are two fine pieces of *Cattleya labiata* in flower, and the usual assortment of late autumn and winter-flowering plants. As will have been gathered from the foregoing, the temperature maintained is that which suits warm greenhouse plants, a little fire-heat serving to keep up the requisite circulation of warm, dry air—this also suiting most greenhouse plants when in flower.

W. I.

**Pears on north walls.**—It is not generally known that such varieties as *Pitmaston* will succeed on a north wall, and will thus give a succession when the fruit in the open is past. The flavour will also equal that of Pears grown under more favourable conditions. There are others equally prolific on the aspect named, and well worth a trial. Of course I do not advise extensive planting of Pears on north walls, my note being to advocate a longer succession of fruits of kinds which make a good show at a season the large fruits are on the wane. *Souvenir du Congrès* does well on a north wall in a well-drained border on the Pear stock. *Marie Benoist* this season is excellent as regards size and crop on the aspect named, and in 1893 and 1894 was of first-rate flavour. When grown thus and the fruits left to hang as late as possible, the season is much prolonged. The well-known *Styrian* or *Keele Hall Beurré* does well on a north wall, but as regards quality, it can only be termed second-rate. Grown thus I think the quality is better, and it keeps well into October. *Emile d'Heyst* also does well, and is of a delicious flavour and most prolific. *Dr. Jules Guyot*, a large, early variety, also does well. *Mme. Treyve* is likewise a good north wall variety. There are others equally good, but in planting, the soil and locality must be considered. In less favoured districts an east wall may be utilised in the place of a northern aspect. It often happens we have a wide selection of fruits for the best walls, but in certain districts a north wall may be made more useful than merely for growing *Morcello Cherries*.—G. WYTHES.

**Apple Bramley's Seedling.**—I think soil must make a great difference in the early cropping of various kinds of Apples. On our light gravelly soil many kinds are most precocious, and varieties which should come in in January are ripe two months earlier. I do not think *Bramley's Seedling* later in fruiting as regards young trees than other varieties, and when penning my note (p. 255) I did not enter into the conditions under

which the trees were growing. I was induced to send the note approving of this comparatively new variety from the quantity of fruit gathered from young trees planted in November, 1893. Perhaps "E. M.'s" trees are in heavier soil. Mine are bushes on the *Paradise* stock and very prolific. I fully agree with "E. M." (p. 303) that standards fruit early and well, and I should say this variety will not need severe pruning in a young state. My young trees were allowed to grow freely. Not having had scarcely any pruning may account for their being more prolific. I find it much better to lift certain varieties about every three years at this season. In the case of small trees requiring to be restricted in growth, this lifting saves hard pruning.—G. W.

**The heaviest Apples.**—While I am no great advocate for monstrous productions in either fruit or flower, I cannot go so far as Mr. James Groom at p. 312 in thinking that large fruit "does positive harm." Some of our grandest Apples produce fruits of great size, and varieties that we cannot afford to be without. Take, for example, *Peasgood's Nonsuch*, *Jubilee*, *Bismarck*, and *Blenheim Orange*. Of the first, Mr. Will Taylor, of Hampton, had a fruit at the *Crystal Palace* recently that weighed exactly 22 ozs. when freshly gathered; *Jubilee*, 17 ozs. Some magnificent coloured samples of *Blenheim Orange* readily sold for 1s. per fruit, and that to a leading fruiterer who regarded them as the finest examples of *Blenheim* he had ever seen. These fruits were remarkable for size and weight, and, not least, their brilliant colour. The same remark applies to many of the varieties grown by Mr. Taylor. The trees producing these grand fruits have had no special treatment; in fact, they form part of Mr. Taylor's nursery stock, and were taken from bush trees not more than 4 feet high on the *Paradise* stock.—E. J.

**Pear Flemish Beauty.**—This Pear is not often met with. Nevertheless, it is one of the handsomest, and when well ripened of good flavour. If grown in a cold clay soil or the roots allowed to descend so as to lose the influence of warmth and air, the fruit is very liable to eat gritty, but when rooting in a medium loam well drained, *Flemish Beauty* is no mean substitute for *Marie Louise*. When in a young state it is prone to make strong wood and few fruiting spurs, and for this reason needs root-pruning every second year until checked by a good crop of fruit. I have this Pear in *espalier* form, and this season the crop is heavy, the fruit very handsome, having a russet skin with a crimson flushed cheek next the sun. One important point in the management of *Flemish Beauty* is always to allow the fruit to remain on the tree as late as possible to prevent shrivelling. In some gardens it is much addicted to dropping its fruit in early autumn, but I have proved that the above treatment will in time stop this.—J. C.

**Canker in Apple trees.**—"S. W. F.'s" note respecting canker appearing on trees of *Blenheim Orange* Apples worked on the *Paradise* stock, whilst trees on the *Crab* stock are free from the affection, is very interesting, as serving yet further to show, whilst so ready to rush hastily to conclusions, how little we know as to the actual causes of canker. The *Blenheim* is invariably very strong and healthy on the *Crab*—is, indeed, one of the healthiest. There is nothing at all singular in its being so healthy with "S. W. F." on that stock. But why should it not be so on the *Paradise* stock? Why, again, are varieties, such as the *Ribston Pippin* and *Wellington*, notably so much cankered on the *Crab* stock usually so free from this complaint on the *Paradise* stock? Certain writers ascribe the canker to a fungus. With these it is always a fungus; indeed, with them all the ills from which vegetation suffers is put down to fungus. But those who hold that canker is but a symptom of poorness of blood, that is, lack of essential food constituents, are much nearer the mark, the obvious deduction in the very diverse cases referred to being this: that whilst the coarse-grow-

ing *Blenheim Pippin* finds what it needs only through the agency of strong-growing and deep-running roots, the *Paradise* stock also to some extent checking or choking natural habit of growth, the *Ribston Pippin* and the *Wellington* prefer obverse conditions, doing best under restriction and finding needful plant food nearer the surface of the soil. That fungoid appearances should manifest themselves after the eruptions in the bark caused by canker have developed is natural enough; similar growth in the form of gangrene may always be found on uncared-for animal wounds. "S. W. F." has a capital opportunity now to test the value of special dressings to his *Paradise*-worked *Blenheim* trees, using potash and superphosphate chiefly and moderately, and in that way see how far lack of essential food elements may be the cause of the canker, or whether it may be due to strangling because of the restrictive nature of the stock. The subject requires much careful consideration and experiment.—A. D.

#### FLAVOUR IN PEARS.

LIKE "W. G. C." (p. 331), I have made notes on the flavour of Pears. There is no other kind of fruit perhaps which varies so much or is influenced more by growth or diverse soils, peculiarities of season, or by general climatic influences as caused by district or elevation. A cold clay soil is about the worst possible for Pears. There may be size in the fruit, and this also produced plentifully, but unless in the very warmest seasons the mid-winter and later Pears will not ripen well. This season I am looking forward to this class of Pear being melting, fine-grained, and of good flavour, thanks to the prolonged and fine autumnal weather, and this from a soil not by any means favourable for high quality Pears in the ordinary run of seasons. I never had *Beurré d'Amanlis* better than this season even when living in a more favourable district for Pear culture. The soil in this garden differs from that of the district which "W. G. C." hails from, which probably makes the difference. But, irrespective of this, my belief is that many people leave this Pear on the tree too long before gathering. If the fruits are allowed to hang until they part readily from the tree the flavour will never be good; in fact, they will be coarse and flavourless and decay early in the centre. Grown as a bush in the open and gathered before the stage just noted is reached the flavour will be good. *Doyenné Boussoch* I gathered exceptionally early in the season. Gathered thus, it was fine-grained and very juicy, the flavour being excellent. Not that I am particularly impressed with this Pear, as it is quickly past its best, and requires very close watching. If allowed to hang until the fruits drop into the hand, as it were, the flesh is mealy and decays rapidly. It is a great pity that this otherwise fine Pear should have this trait, as it is a healthy grower and free bearer, the fruits also being extremely handsome. Even when gathered at the right time, it is melting to-day and off to-morrow. *Louise Bonne* of *Jersey* must also be gathered early. Then we are certain of getting this fine *October Pear* in good condition, otherwise, although the fruits may be of large size and fine colour, they never become juicy and highly flavoured. I remember some years ago having a very fine tree under my care trained to a wall, and which used to bear most profusely. At that time I thought that no Pear should be gathered until when gently raised the fruits parted readily from the tree. When so gathered they never became juicy and highly flavoured, but when a change was made in the time of gathering the quality altered. It is astonishing the length of time even *Marie Louise* will hang on the trees. Often Pears are left hanging so as to eke out the supply, but if left too long it is at the expense of quality. Our latest Pears, which require a long and fine season to develop their high qualities, and which do not ripen until a couple or three months after gathering, must be allowed to hang as long as possible. The true flavour of these

Pears should be developed this season, and this on the more unfavourable Pear soils and district. The assistance of a warm room may be necessary to finish off the ripening satisfactorily.—Y. A. H.

—The notes on Pears that have lately appeared would seem to indicate that there is even a greater difference than usual to be found in many given varieties from different soils and situations. Thus, one writer recommends Beurré Diel as about the best Pear of its season, whilst another condemns it as worthless; and marvellous samples of Duchesse d'Angoulême, very fair in flavour, come from one place, and at another trees on all aspects and of every form fail to produce a single fruit fit for dessert. Occasionally a good word is said for Marie Louise d'Uccle, but as a rule it is a very disappointing Pear; size, colour and aroma are alike good, but the flesh is uneatable. I remember being rather sharply criticised some years ago for advocating the claims of Van Mons Leclerc as a successor to Marie Louise and others of a like season, and am therefore glad to see Mr. Prinsep in a recent number writing very favourably of it. It has only failed with me one season out of fourteen, and that was in 1894, when every fruit went soft and decay set in without any sign of ripening. One cannot of course claim a first-class place for it in point of flavour, but it is very fair in that respect and a great and consistent cropper. Our two best Pears have again been Doyenné du Comice and Beurré Supertin, and we are not likely to have anything better. Possibly the next best from a flavour standpoint are Marie Louise, Thompson's and Winter Nelis, and a contemporary of the latter in ripening—Zephirin Gregoire—is very fair. Beurré Diel is never fit for table, but Glou Morceau does well and is a useful December Pear. Beurré Bachelier has been much better than usual, and Beurré Hardy, extra good, not far behind B. Superfin. A very handsome November Pear, comparatively rare, is Duc de Nemours; it is a great cropper and of very fair quality. A correspondent recently had a good word for Aston Town. This I have not seen for years, but remember some standard trees in an old kitchen garden that produced first-class fruit, not large, but firm, very sweet and juicy and of very pleasant flavour.—E. BURRELL, *Claremont*.

#### HARDY FRUITS IN 1895.

IN taking a survey of the fruit crops for the past season, it must be admitted that it has been one of the most abundant on record, and this, too, after such a severe winter. We are very apt to complain and look on the dark side of things, and certainly in the early part of the season there appeared just cause for complaint, particularly in this district. On the whole, however, the summer has been a good one, and now that the crops are gathered in we are better able to take stock. From north to south we hear of fruit being sold at such a low rate, even the finest samples, as to scarcely pay for the trouble of gathering. I may here give an instance or two showing how useless it is to try and sell poor fruit even at a low figure in a season like the present, when good samples are plentiful. I will first take the Apples. Those who grew the earliest kinds, thinned the fruit, and sent it to market early made fair prices of it. A friend of mine in this neighbourhood who grows Ecklinville, Lord Suffield, and Stirling Castle gathered some of his fruit long before they had attained anything like full size, and sent them to market. For these he was returned 4s. 6d. per bushel. By thus relieving the trees of a portion of the crop, the fruit left grew much faster. The next lot sent up only fetched 2s. 6d., while in the course of a fortnight after, the prices were reduced to 1s. 3d. From this it is evident that the consumer, not the grower, reaped the bene-

fit of the big crop. Seeing that prices in Glasgow were quoted at from 6s. to 8s. per bushel, he thought to try that market, and so forwarded a ton packed in barrels. After a short time he got back 9d. per bushel as his portion after carriage and commission were paid, thus showing that Apples must have been very plentiful even in the north. It would appear from this that Apple growing in a season like the present is a complete failure, and so it would be unless better care were taken to select the right varieties and put them on the market at the proper time. To pack early soft kinds that are ripe into barrels and send them a long distance is certainly a mistake, as they are sure to be rolled about when transhipped. Many Apples have been sold in this district during the autumn for about 6d. per bushel, but they were small, inferior samples only fit to grind down to make cider. Those who are about to plant this autumn with a view of growing for market would do well first to consider which varieties are most suitable for that purpose, whether they are able to get them forward enough so that they may be put on the market early, or grow the later kinds that will travel some distance without being bruised. We have seen that the early Apples commanded the best price, while the midseason kinds were not worth gathering. Unless long-keeping kinds are grown, it would be well for growers to confine themselves to large, early and free-bearing kinds. Those named above are all good, and to these might be added Pott's Seedling, Frogmore Prolific and Loddington, all of which are first-rate. There are of course others, but it is not well to grow too many sorts where bulk only is needed. If I were asked which was the best Apple to succeed these, I should have no hesitation in saying Lane's Prince Albert. This is certainly a poor man's variety, being a good grower, of hardy constitution, and a sure cropper. Nor is this all, for the fruit grows to a good size, keeps well, and is a splendid cooker. Midseason kinds—that is, those that are in use during October, unless they have some special merit to recommend them, such as colour and size, are not worth growing. Long-keeping kinds will always command a price even when the American Apples are plentiful. Cox's Orange Pippin, Northern Greening, Royal Russet, Wellington, Brownless' Russet and others that keep sound till March or April, particularly when well grown and of good quality, are sure to sell well, and as most of these are prolific bearers, they should be planted in preference to such as come into use during October and November. Nurserymen as a rule grow those varieties for which there is the greatest demand, and those who grow for the trade only confine themselves to a few kinds which meet with ready sale. Any who are desirous of planting with a view to growing for market should bear this in mind, and first ascertain what varieties do best in the district. Some Apples may look well in shop windows or in the market that would be useless to the grower from a commercial point of view, they being such shy bearers. As a rule nurserymen fruit but few trees, their object being to grow the plants for others to fruit, though some, as gardeners know, grow trees large enough to produce a crop. Especially is this so with the leading retail firms. It would be well, therefore, if intending purchasers would visit these in the autumn, and not only see the fruit growing, but the habit of the trees, size of fruit, and any other peculiarities there may be concerning them. Turning from the Apple, I will next take the Plum as being the most serviceable on account of the numerous uses it may be put to. Pears no doubt would be preferred

by some, while others would have a fancy for Peaches. Each and every fruit is useful in its way, but those demanding our attention most should be such as are of the greatest benefit to the public at large, as they are of the greater commercial value. Those of us who have only seen fruit as grown in private gardens can have no idea of the extent it is grown for market, but for once the supply has far exceeded the demand to be of any real profit to the grower. It seems strange that Damsons should be offered in the markets in the midlands for far less money than they could be gathered, and yet people would not buy simply because they did not know how to preserve them cheaply. No better plan could be adopted than cooking them in their own juice in jars and sealing them down while hot. Yet how few poor people know of this, and allow a fruitful season like the present to pass by without taking advantage of it. Were our home-grown fruits husbanded in the best possible manner when we have good crops this would do more to shut out foreign competition than all the laws on protection that could be made. That our climate is suitable to the growth of such fruits all must admit, yet when we have a plentiful season fruit goes begging, while thousands of people scarcely ever taste it. Some years ago French Beans were a great rarity in the winter; now in this district they are almost as common with the poor people at Christmas as they are at the end of August, and this simply because they understand the art of preserving them in brine. Black Currants were the most abundant crop in this district I ever saw, and they realised a fair price simply because so many are used for jam; and the same may be said of all bush fruits. Pears, not being in such demand as Apples, are of course not so much grown, but the wonder to me is that more baking or stewing varieties are not cultivated, seeing that they are far hardier than the others and remain in condition for such a length of time. Catillac this season is very fine, and will no doubt be very serviceable for some months yet.

We may therefore congratulate ourselves on not only having had plentiful crops of soft fruit that has either been used or preserved, but that our store-houses are well furnished for the winter and will give us a supply till far on in the spring. H. C. P.

**Apple Warner's King.**—I notice some catalogues give the season of this Apple as from October till February. Will any correspondent, who has had it some time after Christmas, kindly say what are the conditions of growth conducive to such keeping? Mine are nearly always all gone by the beginning of October, and the few that remain over soon spot badly and are comparatively worthless. It is matter for regret that there are so many Apples of about the same season, and, as a rule, such sorts as Lane's Prince Albert, Blenheim and Wellington might be used more extensively in new planting, to the exclusion of so many soft kinds that are useless after, say, the middle of October. Of the midseason sorts, the best keeper with me is Yorkshire Greening; it is also a splendid cropper on young trees, and, despite its somewhat unprepossessing appearance, is a splendid cooking Apple.—E. BURRELL, *Claremont*.

**Morello Cherries as bushes.**—The Morello grown as a bush with a short stem, and kept to a certain size, is valuable, as the fruit hangs well and is less subject to the attack of birds than the sweeter kinds. Not only is the Morello good in this way, but the Kentish Red is equally good and one of the best for tarts or cooking. The value of the Kentish Cherry is its long-lasting properties, as if the trees are broken in any way they soon make new growth. But the Morello and Kentish

Red should be grown on the Mahaleb stock, as they are more prolific and bear finer fruit of better quality. Though these varieties do well in standard form, they are not so easily managed, the pruning is more difficult, and the roots, which should be near the surface, cannot be so well looked after. The trees, when dwarf, require to be kept well thinned or pinched in the head during growth, as many of the best fruits will then be borne on spurs, and by free admission of light and air there will be better fruit. On trees with compact heads the fruit can be protected. It also colours better and the trees present a neater appearance. The Wye, or old type of Morello, does well when grown in the open, but I do not care for it, as the fruits are small and very late.—G. WYTHES.

### PRUNING ILLUSTRATED.

TO THE EDITOR OF THE GARDEN.

SIR,—I have a suggestion to make which, if carried into effect, will, I believe, prove fruitful in more senses than one—it will give an opportunity for those who have a liking for photography to engage upon a work of great interest, and a profitable one to boot. The idea is to produce a series of photographs with the object of showing in a graphic manner the art of fruit tree pruning, an art that needs cultivation, as may readily be proved by a passing glance in any district throughout Great Britain where fruit trees have been planted. It is the exception to find that after having been put in the ground they have received proper treatment and attention, and, from cause to effect, a very large proportion of the fruit we see is of inferior size and quality and the majority of the trees and bushes are "rank wild," yielding immature fruit and harbouring disease in some form or other—doing more harm than good.

If a series of illustrations from photographs, showing how trees are properly pruned, were published from time to time in THE GARDEN, with descriptive notes by a competent gardener, they would provide a much-felt want, and if produced afterwards in, say, an annual volume, a work would be issued that would find a large sale not only in England, but in the colonies where fruit-growing is now so extensively carried on, and where the want is greater still of a work that will show more plainly and clearly than words can possibly do how to prune. The work may be undertaken at once. The camera should be guided and directed by one capable of selecting suitable specimens for the purpose. If not an expert in both arts, the owner of the camera may obtain the assistance of a gardener who would take a joint interest in the object to be attained. Trees and bushes would have to be shown in all stages and conditions of growth. Views taken now would present them with the summer growth after the crop; this would come out best when some of the foliage has been shed. The next of the series of the views would be the same trees and bushes after pruning, then another series with bud and blossom on, and yet another to display the effect of proper cultivation—the crop. To contrast with good cultivation I would have views also of badly pruned, over pruned or neglected specimens. There is nothing so convincing as a good object lesson. Whilst in Australia I implored one of my friends to prune his trees. He was showing me with great pride his Peach trees towering high above his roof. The fruit, few and far between, was very small, but not until he stood by one of my trees loaded with fine fruit, the branches propped up, and every Peach within arm's length from the ground, would he heed what I said. He then admitted not one of his great trees three or four times as big had half the quantity of fruit on, or anything like the quality. "There must be something in what you say," was his comment. There are many who need convincing of the necessity for pruning, and many more who would prune if only they knew how to do it. I have sketched out a series of views extending over a year, but the work should not stop there; it should show

the progress, both good and bad, over three or four years, or even longer, made by the same trees and bushes.

In addition to the picture of the whole tree, there should be details; for instance, a portion of a branch, before pruning and after, large enough for the buds to be distinctly seen, and shoots to be nipped back may be shown by a branch that has not been nipped and after it has been nipped. Summer and winter pruning will then be dealt with, the after shoots following summer pruning that have to be cut out. Cuttings should also be shown at a size large enough to display the features to be attended to; the cutting as taken off, and with the buds cut out and shortened ready to place in the ground. Then there are underground operations to be performed in root-pruning. Many who have their doubts about the proper way in which to prune the branches have absolute fear about touching the roots; those fears are to be allayed by being shown first how the roots appear when exposed to the view, and then how they have been brought into subjection by the knife. The work may be commenced at any season of the year. If confined to the most common varieties only, Apples, Pears, Plums, Cherries, Gooseberries, Currants and Strawberries, the work would be most interesting and valuable; it may, however, be carried much further. The views should be clear and well defined, and in most cases some object should be introduced—a figure, a spade, a wheelbarrow, anything to convey an idea of proportion. Cuttings shown in a hand holding a knife would need no description as to thickness or length. I have photographs of enormous trees, but no one could judge of their size from the photograph because there is no object taken with them by which the proportion can be judged. In the case of trees the age should be stated, approximately if not exactly, and in all cases the time of year when the view is taken should be named and the district. There is a considerable difference in the season of the year between the sunny south and the far north of England.

The suggestion may be put into practical shape and carried into effect on the lines of a competition: selections to be made for reproduction from views contributed by those who may enter into the spirit of the competition.

Wetherby, Yorks.

C. R. FENWICK.

### VERY LATE PEACHES ON WALLS.

LATE Peaches are not always so good as they have been this season. At the end of October I gathered fruits of Golden Eagle, and the flavour, if the season be taken into account, was not at all bad. It may be said, why advise the culture of the very late varieties in our variable climate? There is a demand for late Peaches, and good prices are obtained. "Y. A. H." at p. 312 says that he obtained 18s. per dozen for Sea Eagle, but if they fetched half that price it would be worth while to risk a season or two and plant late Peaches. I am not concerned about market prices, and cannot write on this point like "Y. A. H." or "W. G. C." My remarks as a grower of these fruits for private use may not be out of place. I find these very late Peaches most serviceable, and anyone who has a large and varied dessert to supply will also find them useful. The flavour cannot be compared to that of August fruit, but appearance goes a long way. Such kinds as Princess of Wales, Golden Eagle, and Walburton Admirable are not badly flavoured, and even in the most unfavourable seasons the trees can be given special attention by placing lights or sashes against the trees or sheltering them at night with mats or canvas to throw off moisture and early frosts. Late Peaches, such as Salway, need more than ordinary care. I do not advise it for open walls, as it is not reliable. In a cool house or case it deserves a place, and I can with confidence recommend it for very late dishes; indeed, I have seen this variety if carefully wrapped in tissue paper keep till Christmas when grown on a wall with a glass coping in the

southern parts of the country. Lord Palmerston is one of the very late varieties, but I do not advise it for open walls. It is a very large fruit, but of poor quality and not reliable for general cultivation. Barrington grown on an east wall in a warm soil is preferable; indeed, this variety may be had well into October grown thus if planted in suitable soil. The same remarks apply to Bellegarde or French Galande, and it rarely fails in the worst autumns. Given a favourable season, Walburton Admirable is one of the best of the late section. I have had it very good this season, also in 1893, on a west wall. It should be stated that the soil is very light and the garden sheltered. In localities where the very late kinds are not reliable, such kinds as Bellegarde, Barrington, and Sea Eagle will give a good return. In a northern exposed garden I recently saw very fine crops of late Peaches, the trees growing in raised borders. Most of the trees were standards with 5-foot stems, dwarf dessert Cherries being planted between. The only objection to the Cherries was their liability to attacks of black and green-fly and the difficulty of keeping the trees clean. There are other kinds besides those named, but they lack flavour, though prolific. The half-dozen named will, when grown well, be found valuable. G. W. S.

### SHORT NOTES.—FRUIT.

**Apple Domino.**—This is a free-growing, useful early kind. I consider it superior to Ecklinville and several others of this type. In this garden, where Lord Suffield is not satisfactory, Domino is a success. Recently I observed some young trees in a nursery at Darnham Market loaded with large handsome fruit. With me it keeps till November.—J. Crook, *Forde Abbey*.

**Cleaning Vines.**—What is the best mixture to paint over the rods of Vines after they have been washed with soapy water? Gishurst compound I cannot get here. I use a mixture of sulphur, nicotine and strong soapy water. Is there any objection against it?—R. KATZER.

\* \* \* The mixture you use is suitable. If you add a little clay to make it stick to the rods it will be all the better.—Ea.

**Spot on Figs.**—I have a Fig tree (sort unknown) planted against a wall in the Apricot house, in which forcing begins about the end of January. Every year the tree is covered with fruit, which grows up very quickly till a brown spot makes its appearance upon it. The Figs cease growing and soon afterwards they drop; this has happened two years in succession. The tree is healthy and is not syringed. Could any reader of THE GARDEN tell me what the disease is?—R. KATZER.

### GARDEN FLORA.

#### PLATE 1040.

#### CATLEYA HARRISONIÆ.

(WITH A COLOURED PLATE. \*)

ALTHOUGH one of the oldest Cattleyas in cultivation, a glance at the accompanying plate is sufficient to show that it still merits attention on account of its beauty. Its free-blooming propensities and the ease with which it may be grown are additional recommendations, so that, taken all round, it may be styled one of the most generally useful in the genus. The pseudo-bulbs on strong plants attain a height of about 20 inches, and each bears at the top a pair of light green leaves very thick and leathery in texture. The flower-spike issues from between these at the time the plant is finishing its growth. Being rather erratic in this latter proceeding, no special time can be named as its flowering season, for of ten before one spike is over, the eyes at the base start

\* Drawn for THE GARDEN by H. G. Moon in Mr. Sander's nursery. Lithographed and printed by Messrs. Joseph Mansell, Limited.

MR. GREEN  
NOV 15 1919

CATTLEYA HARRISIANA

afresh, another pseudo-bulb is made, and this generally throws a spike in accordance with its strength. A good deal of water is required by this *Cattleya* all through the season, and it is often kept too dry at the roots during winter. The compost should on this account be free and open, good fibrous peat broken in lumps as large as a pigeon's egg, with most of the earthy portions sifted out, forming the chief ingredient, the rest being made up of chopped Sphagnum and rough potsherds or ballast. The pots must be filled to about three parts of their depth with crocks, a couple of inches of compost sufficing for the largest plants. In this open, well-aerated medium the roots run freely, and are consequently healthy and long-lived. In potting, the leads must be kept as far as possible from the edges of the pots, it being sometimes advisable to notch the rhizomes in order to bend the leading growths back towards the centre, for no *Orchid* gets bare more quickly than *C. Harrisoniae*. All the old peat should be picked or washed out from among the bulbs, and any roots that are seen to be decayed cut away to make room for the new ones. This will prevent the hard mass of roots and old compost collecting together, making it difficult to water the plants without getting them soddened. The *Cattleya* house or intermediate temperature suits this species well, allowing it to have its own way in the matter of resting and growing, encouraging it when the growths are moving, and keeping it as cool and quiet as possible at other times. No watering overhead is necessary, in fact it is dangerous, especially when the new growths are about half finished and the young leaves form a kind of cup, wherein the water is apt to lodge.

Newly-imported plants of this *Cattleya* are often badly infested with a soft white scale, and this must be removed at once, or the probability is they will never be clean. The insects are usually very thick about the rhizomes and under the scaly sheaths of the bulbs, and the work of cleaning must be very carefully done, using a stiff brush or a pointed stick to dislodge them from the hard, woody parts, and carefully sponging the leaves with tepid soapy water. The blossoms of the typical *C. Harrisoniae* vary considerably in size and the number produced on the spike. They are usually about 4 inches across, the sepals and petals being soft purplish rose, the lip lighter in ground colour and stained with yellow. The segments, being well thrown back, show off the blossoms to the best advantage, and these last from three to four weeks in good condition. It is a native of Brazil, introduced about 1835.

*C. H. SUPERRA* is a large and well-formed variety of the type, the sepals rather narrower, but very rich in colour, the lip pure white in ground colour with a ridge of yellow.

*C. H. VIOLACEA* is a deeper coloured form, the segments all being bright rosy purple, the lip margined with white. Other varieties are candida, with white flowers; *Rogneriana*, deep purple; and *maculata*, which has the segments spotted with bright purple. H. R.

**Flower gardens in winter.**—Flower gardens in winter, as a rule, present anything but an attractive appearance; this is the more unfortunate, as the owners of them usually reside at their country seats the greater part of the winter. Much might be done, however, to brighten and adorn the beds from October to May by planting ornamental shrubs and conifers in small, shapely specimens. At a small private place near here the flower garden is always worth a visit, even in the most wintry weather, some of the most conspicuous plants employed being gold and silver

conifers, tree lilies, variegated Box, *Cryptomeria elegans*, the various forms of *Euonymus*, Golden Hollies in quite a small state, and *Aucubas*. A little care in the arrangement gives a very pleasing effect, as the shrubs present a great variety of colour and are quite charming viewed from the sitting-room windows on a sunny day. In April it is necessary to remove them to a cool border or home nursery, and propagation must be practised every few years to keep the plants dwarf.—J. C.

## THE WEEK'S WORK.

### HARDY FRUITS.

**PEACHES AND NECTARINES.**—This being the most important month to the fruit grower as regards hardy fruit selecting, planting, and filling up spaces occupied by old, worn-out trees or useless varieties, no time should be lost in making an early start, so that good material may be secured and the trees placed in their growing quarters as early in the season as possible. Peaches and Nectarines are the first that require attention, as few fruits give a better return if given ample attention and grown on a favourable aspect. During the last few years we have had specially favourable summers, also good autumns for ripening the wood. This doubtless will have caused more interest to be taken in these trees. They have this year made a later growth than usual, but owing to there being no late spring frosts the growth is better matured, and planting need not be delayed. I never saw trees look better, the wood being firm and not coarse, as one sees in wet seasons. I noted the value of early planting, also the materials required to secure the best results, at p. 341, so I will now only add a few words as to position and variety. Peaches in the most favoured parts of the country do well on a west or south-west aspect, while in others a wall full south is necessary. Here I get the best fruits from a south-west wall, and by having trees on a west aspect in such years as we have had recently, the season is prolonged—an important point where a long supply is desired. I will name a dozen varieties suitable for early, midseason, and late fruiting. *Early*: Alexander, Amsden June, Hale's Early, and Condor. *Mid-season*: Dymond, Grosse Mignonne, Royal George (on warm walls), Noblesse, and Crimson Galande. *Late*: Barrington, Princess of Wales, and Walburton Admirable. This is a select list, but it is reliable. I admit Royal George mildews badly at times in wet seasons, but it is too good to omit. The following Nectarines are reliable: Rivers' Early, Advance, Lord Napier, Humboldt, and Pine-apple. Newton is also good for late dishes.

**APRICOTS.**—These trees to do well require similar attention to Peaches and Nectarines; indeed, I think more so, as I find by early planting before the leaves fall better results are secured. Of course, it is impossible to get trees in full leaf from the nurseries. Of late years the trees when sent are none too large, but to a certain extent this is not the grower's fault, as the young growths are so often cut down by May frosts. The spring of 1894 was the most disastrous, as the young growths were so injured that the trees in some cases were lost. This year it is the reverse; growth is all one can desire. As most growers of these trees know, the Apricot suffers much from drought during the growing season, and this points to the necessity of early planting, these trees being the first to start in the spring. As regards soil and position, much the same remarks apply as to Peaches, but though the trees will in a sense stand flooding weekly during growth, they require efficient drainage, and in heavy clay soils should have a liberal addition of lighter material with ample drainage, or, what is better in gardens where Apricots fail, a raised border. To plant as advised when in leaf I have found it advantageous to purchase one season and grow on a low wall or even between larger trees, replanting in the permanent quarters the next. In this way the trees can be

lifted early and will do grandly the next season. As regards quality, Moorpark must have the leading position, but of late I have not planted it, as it cankers so badly. Hemskirk is more reliable and very little inferior in flavour. I find such kinds as Powell's Late and Frogmore Early very good in every way indeed; I think such kinds as Powell's and Large Early should be given a trial. Oullin's Early Peach, a very early kind, not large, but good, a very free and hardy kind, not much given to canker, may be added to the list.

**CHERRIES** are less fastidious as to soil and position, doing well on east and west walls. They are valuable, as they come in advance of all other fruits, and a few of them will repay culture on a north wall in favourable localities, as they then give a longer succession of fruit. Cherries, like Apricots, start very early into growth, and the same remarks are applicable as regards planting. The trees delight in a good loamy soil with efficient drainage. They soon suffer from drought; indeed, more so than other fruits, with the result that black fly and red spider soon play sad havoc with them. In the case of Cherries I do not advise raised borders, though deep planting should be avoided. Most of the Cherries do best on the Mahaleb stock, especially the Duke section and the Morello and Kentish varieties. The following may be termed a select list and noted for cropping and quality. They ripen in the order named. *Early Rivers*, black; *Bigarreau Jaboulay*, red; *Frogmore Bigarreau*, yellow; *Governor Wood*, red; *Bigarreau de Mezel*, pale red; *Emperor Francis*, red; *May Duke*, dark red; *Archduke*, red; *Bigarreau Napoleon*, yellow; *Late Duke*, red; *Florence*, pale red; *Black Tartarian*, black; and *St. Margaret* or *Tradescant Black Heart*, a grand late hanging variety for wall culture, and of good quality.

**PLUMS.**—These do well in the open as bush trees and standards. Much may be gained by early planting if the soil is light or on a gravel subsoil. There is a wealth of what may be termed midseason Plums, and an east wall devoted to later varieties will well repay for space occupied. Even large old trees pay for a shift if not fruiting satisfactorily. Such kinds as *Coe's Golden Drop*, which hangs well into October, *Belle de Septembre*, and *Monarch* are well worth including in the list of wall Plums for late supplies, and the well-known *Jefferson*, one of the finest Plums grown, is valuable for midseason fruits. *Oullin's Golden Gage*, *McLaughlin's Gage*, *Transparent Gage*, *Kirke's*, *Reine Claude de Bavay*, and *Late Transparent Gage* are all good, whilst for early supplies, *Early Prolific*, *Czar*, and *Early Orleans* are good croppers. For cooking, *Victoria* is the best all-round variety. *Pond's Seedling*, with *Prince Englebert* and *Wyedale* for late use may also be added.

**APPLES AND PEARS.**—These should now receive attention. I find the wood is fairly well ripened, and such being the case, there will be little fear of the bark shrivelling. Out of hundreds of varieties of Apples, the well-known *Cox's Pippin* still stands at the head of the list. In selecting Apples and Pears much depends upon the soil, shape of trees, varieties, stocks, and other details. Whatever the soil or variety, it is well to plant before severe weather comes on; besides, by early planting a better selection is secured. Pears lose their leaves sooner than Apples, and though later than usual, there need be no delay. Pears are admirably adapted for cordon planting. For dwarf trees the Quince stock may be relied upon. They also bear very early and are most prolific. The Pear stock is used for trees required to grow freely or cover a large wall space. Pears also do well as espaliers if the soil is chalky or on gravel. The Pear may with advantage be grown in espalier form. Trained horizontally and allowed to make four or five tiers, Pears form a good dividing line. Pears on the Quince may be given a limited space, and should not be planted deeply. In planting these trees in the open, it is well to secure against wind. Wall trees or cordons must be allowed to settle, so that only a temporary support need be given. It is important that

newly-planted trees of all kinds should get a mulch or cover of straw short litter after the soil has settled down to protect the roots from severe frost.  
G. WYTHES.

### KITCHEN GARDEN.

**VEGETABLES AND THE SEASON.**—Many vegetables are turning out anything but satisfactory this autumn, owing no doubt to the fluctuating character of the past summer. Mention was made by Mr. Wythes in last week's issue of the ungainly size of Beetroot from ordinary sowings. Our sown batches are larger than usual, but those that were transplanted owing to blanks in the rows have grown to medium dimensions only, the colour is deeper and doubtless the flavour better than that of the coarse large roots. The one thing needful in Beet intended for use in the salad bowl is small size, as large slices look bad when sent to the dining table. I really think that in all gardens where Beetroot is esteemed it would pay to transplant a row or two with plants thinned from the last sown lot; these if put out on poor land and kept moist for a time will make just the right sized roots for slicing up. Dell's is still a popular Beet, but my favourite both as regards size and colour is Veitch's Selected Red. Brussels Sprouts and all the Kales have run unusually high this season, and having made a deal of soft late growth, were more or less nipped by the severe frost at the end of October, every vegetable being saturated when it came. This being so, it will be well to watch the Scotch curly Kale, and if the crowns show signs of decay, let them be cut and used at intervals. The same remarks are applicable to Brussels Sprouts also. It will also be advisable to go through the quarters of Kale on a dry day, and remove any decaying leaves from the base of the stems, as by leaving them others become affected.

**CHOU DE BURGHLEY.**—This will be found excellent for a change in the dining room at this season, and for a couple of months to come. The flavour of this Cabbage is quite distinct, its beautiful colour when well cooked being also greatly in its favour.

**CLEANING ASPARAGUS BEDS.**—The sooner now all Asparagus beds are divested of their ripened growth the better, as then the surface soil can be cleared of weeds which have grown since applications of salt became impracticable. Asparagus beds are often mown over in autumn, and in large gardens where many long beds are grown, this mode of clearing is almost imperative, as cutting off the stems with the knife would occupy too much time. In small gardens, however, where only a limited number of beds exists, I prefer to use the knife, as often the scythe tears the stalk instead of cutting it clean through, and the rupture extends right down to the crown, which is an evil. Autumn or winter mulchings are still practised by some gardeners, and that, too, when the beds are composed of strong loam and lie at a low elevation. On this account beds often suddenly deteriorate and even die off altogether. But while not approving of surfacing the beds with rotten manure at this period, I certainly think that the crowns and roots, the best of which lie nearest the surface, are benefited by a liberal covering of light manure. I always spread old hot-bed material over those under my charge, first applying a broadcast sprinkling of some good fertiliser, but then the soil is light and the subsoil well drained, and the roots never get too much moisture even in the wettest of winters. Many still entertain the idea that good Asparagus cannot be grown without the aid of plenty of salt sown on the beds at frequent intervals, but from experience I am convinced that that is more imaginary than real, as some of the very best growers seldom or never use it. However, salt being a good weed eradicator, a dusting of it may well be given as soon as the refuse is cleared off and before any mulch is applied. Care is needed in raking the beds, as after a mild genial autumn young shoots frequently spring up and are easily injured. In making new beds avoid elevating them to any great degree

and having a deep trench between them, as on light soil this has a tendency to drain much of the needed moisture away from the roots, and on heavy land the water drains into the trenches and there often stops to work mischief, instead of gradually percolating evenly, though slowly, through the bed, and in due time escaping. Where old semi-exhausted beds are being forced, avoid planting in any of the old material; choose a new site entirely and use the old plot for other vegetables. The finest Peas, Beans and Cauliflowers may be grown on old Asparagus beds, bush fruit also doing well.

**SOWING PEAS.**—To some it may seem early to talk of putting Peas into the ground, but where the old practice of sowing in autumn is still adhered to the present time is about the best. Some ignore autumn sowings, but certainly where the border is light and warm and the situation good, and where, moreover, time can be bestowed on the arduous task of keeping mice from destroying the seed, there is a gain in it. Peas transplanted in spring, be they ever so gradually inured to the open air, are apt to suffer should snowstorms and cutting, frosty winds prevail just after putting them out, say, in March; whereas those sown now acquire a hardy constitution and readily respond to finer weather and longer days in February. Some method of protecting the seed from excessive rains should be devised, nothing answering better than wooden troughs, which can be stood between the rows when the weather is fine. I have found the plan I advised for the earliest spring sowings—namely, that of slightly raising the soil of the border where the drills are to be drawn, and of sowing fairly shallow. Treated thus, the seed is kept from rotting until germination takes place. If the ground is fairly rich, add no manure, but if any is necessary, use Mushroom manure in preference to that from the farmyard, as the latter encourages a growth which is prone to injury from frost, and also apt to fall a prey to basal rot. In regard to the varieties most suitable for sowing at this date, any of the small round-seeded sorts, such as William Hurst, Chelsea Gem and English Wonder (a Pea very highly praised by many good growers) may be depended upon. For my own part, I think Chelsea Gem cannot be equalled. Let the distance between the rows be the same as the height of the Pea, this admitting plenty of light and sun to the roots and haulm in spring. As soon as growth shows itself through the ground place small Yew or Fir boughs on either side of the rows as a means of shelter. I always sow Chelsea Gem in a cool pit at this season, and gatherings are then forthcoming from the middle to the end of May. Soot and lime must be used freely, as slugs often work mischief in mild winters. Sparrows likewise must be watched for, or a raid by them of a few days' continuance will blast the cultivator's hopes. A little leaf-mould strewn in the drills before the ordinary soil is raked in will assist root action.

J. CRAWFORD.

### NOTES ON PLUMS.

THE following notes on Plums which we are enabled to publish through the kindness of our correspondents will doubtless prove interesting to our readers. They are from all parts of the United Kingdom. The following are the questions which we submitted:—

1. *The value of the Plum as an orchard tree, and how far its culture deserves extension, and in what soils?*
2. *Your opinion as to the value of new Plums, including those of Japanese, American, or European origin?*
3. *The best flavoured Plums?*

There are many extensive Plum orchards near this place, the chief sorts grown being the small black, red, and grey varieties, which are generally very productive, and mostly used for preserving. Some growers are now introducing newer and

better sorts, the favourites being Orleans, Pond's Seedling, Red Magnum Bonum, Kirke's, Washington, Diamond, and Victoria.—W. SANGWIN, *Trillick, Truro.*

The Plum is largely grown in this district as an orchard tree, but mainly the common Pershore or Egg Plum, as it is locally known. Rivers' Early Prolific, Victoria, The Czar, Cox's Emperor, Pond's Seedling, and Early Orleans are also grown. I consider it would pay to plant more largely the better varieties, and especially Damsons, as there is always a demand for them.—J. JUSTICE, *Nash Gardens, Kempsey.*

Plums are not grown as orchard trees to any extent in this district, growers preferring bushes or pyramids, being more easily managed and not so liable to injury from storms. As bushes or pyramids they give good returns. On the sides of the Tamer there has been a great extent of old woodland cleared and planted to fruit trees (mixed) with good results. Plums should be more extensively planted, as the fruit bears carriage well, and, if graded and carefully packed, reaches the markets in good condition and fetches good prices. The best sorts of Plums for such planting are Victoria, Denyer's, Czar, Rivers' Early Prolific, Pond's Seedling, Diamond, and Orleans. Our best-flavoured Plums, all on walls, are Denniston's Superb, Coe's Golden Drop, Jefferson, Kirke's, and the Gages in variety.—FRANK YOLE, *Emlshigh, Tavistock.*

The Plum has an undoubted value as an orchard tree, but for profit free-bearing sorts must be chosen, and a good central position within reach of the orchards for the disposal of the fruit without the risk and heavy expenses involved in railway transit. In West Wilts Plums are grown as orchard trees. There is a very good local sale for Plums, but whether it would be a good investment to extend their culture is a doubtful question, especially with the present foreign competition. Those at present grown in quantity are only suited for preserving, and are known as harvest Plums. Green Gages are planted by some, and as standards when they are in a matured stage they fruit very heavily, and are always quickly bought up in the open markets, where the bulk of the Plum crop is disposed of to the masses. Where Plums grow moderately and fruit freely in soil of an open, sandy nature with a gravelly bottom. In deep clayey land growth is often too free, but the fruit produced on such is large, well-coloured, and good in quality. In soil overlying chalk or limestone Plums sometimes do well, but I am inclined to the belief that in "brashy" soil, to use a local phrase, Plums may be most profitably cultivated in orchard form. Of modern Plums, I think the late autumn ripening kind, Monarch, is likely to prove a decidedly popular and an invaluable one, there being so few dark Plums in use at the time, and although not so richly flavoured it should make a good companion to the Golden Drop. Those having superior flavour include the majority of the Gages, and especially the Transparent, Bryanston, Golden Drop, Reine Claude de Bavay, and Oullin's Golden. Others claiming first rank for quality are Jefferson, a fine yellow August Plum, Kirke's, Peach, Prince Englebert, Angelina Burdett, and De Montfort. The secret no doubt in getting full-flavoured and large fruit is to thin early in seasons when the trees are overlaid. When allowed to remain on the tree as thickly as they set, size and quality both are absent; in fact, for market, the best kinds are no better than commoner ones in both respects. This applies to any form of tree, standard, bush, or espalier wall trained. Gathered in a green state before they overtax the trees, they may be profitably employed for domestic purposes, and it would be work amply repaid if they were thrown away in the event of there being no use for them in that condition.—W. S., *Trowbridge, Wilts.*

I consider the Plum to be one of the most valuable fruits for orchard cultivation, and it is very much in evidence in the orchards in this neighbourhood. Victoria is found the most remunerative in this locality; thousands of standard trees

of it are to be seen in the orchards in the Clyde valley, and which are this season bearing enormous crops. These orchards are well drained and sheltered from high winds; soil, light sandy loam. I consider Green Gage and Coe's Golden Drop the best flavoured.—J. GRAHAME, *Coltneis, Wishaw*.

Victoria, Green Gage, and Kirke's are the varieties mostly grown in the open, while on the walls, in addition to these, are grown Orleans, Jefferson, Golden Drop, Pond's Seedling, Magnum Bonum, and Washington (old varieties), and Monarch, Early Orleans, and Rivers' Early Prolific (new varieties). These last three I believe to be excellent varieties. For flavour the best I find are Green Gage, Golden Drop, Jefferson, and Kirke's. For an open air cropper the Victoria is by far the best, but I would not advise the extension of Plum culture in this district. It is too cold and very windy, and the crop very uncertain. Only with the help of walls or good shelter would I advise planting of Plums.—R. C. WILLIAMS, *Crosswood Park, Aberystwith, S. Wales*.

It cannot be said that the Plum succeeds well in this district. We are very often without a crop when I see large quantities in the markets from the growers in England. With the exception of the Damson there are very few Plum trees to be found in the county, especially the southern districts. The Damson is very extensively grown in a district in the middle of the county, every farmhouse and cottage having its Damson orchard, and in the season if there is a good crop it is one of the sights in the local markets to see the long rows of peasant women with their baskets of Damsos. There is a local tradition to the effect that the Damson was first brought into the district by a monk of Slebeck from Damascus. The Damson district of this county is situated on the coal measure chiefly, but ramifies on to the old red sandstone, silurian, and limestone. The Damson appears to do equally well on all. The best Plum for the district is decidedly the Victoria, after that Jefferson and Prince Englebert. I find the three varieties named to be the only ones worth growing here. I should depend upon the Victoria for crop, and plant a few of the other two for variety. I have tried many other sorts, only to fail with them, generally through their cracking, as the soil is rather light and well drained. Our fruit trees are continually getting covered with Lichen to an extent that is unknown in the fruit-growing districts of England. I have not tried the newer varieties of foreign Plums.—G. GRIFFIN, *Slebeck Park, Pembroke*.

I consider the Plum to be of considerable value as an orchard tree, because it is possible to select varieties especially adapted for the precise kind of soil one has to deal with. Owing, however, to the difficulty of finding a good market for the fruit when the crop is a good one, I think it undesirable to largely extend the culture of Plums except in soils and positions where Apples and Pears do not thrive. In the light warm soils around Warwick the following varieties succeed well as orchard trees: Pond's Seedling, Prince of Wales, Orleans, Goliath, Diamond, Monarch, White Magnum Bonum, Early Favourite, Prince Englebert, Early Mirabelle, Green Gage, Jefferson, Transparent Gage, Denniston's Superb, and Purple Gage.—H. DUNKIN, *Warwick Castle*.

Plums do well in this neighbourhood, when they escape the spring frosts, but as the bloom is killed three years out of four, they are a very hazardous crop. I have some trees on high ground in a calcareous loam which bear good crops almost every year. In that situation Plums pay. Victoria, Pond's Seedling, Diamond, and Syston White—a local Plum similar to Pershore—do best, also Blecker's Scarlet. The best flavoured Plums here are Jefferson, Coe's Golden Drop, Green Gage, and Transparent Gage. I have had no experience with the newer varieties of Plums.—J. LANSDALL, *Barkby Hall, near Leicester*.

In regard to the value of the Plum as an orchard tree, it is no doubt a profitable fruit to grow for sale, particularly when good markets are within easy reach. I think, however, Plums pay better

in midland and northern districts where the markets are not so glutted at one particular time than in, say, the Kentish and Sussex gardens, which are within such an easy distance of London and where such enormous quantities are grown. It is the very heavy crops and consequent glut in the London markets that make Plum growing unprofitable in those counties. In my opinion the finest flavoured Plums are Kirke's, Jefferson, Reine Claude Violette, Denniston's Superb, MacLaughlin's Gage and Coe's Golden Drop when well ripened; the last, however, unless under glass, does not often attain to maturity in this district. For cooking I do not think the Victoria can be beaten. My experience is that a medium loam of fair depth is best for Plum growing. When the soil is strong and retentive of moisture gross growth for years and often permanent unfruitfulness, in spite of root-pruning, are the result. It is astonishing how well Plums will do on light sandy soils if heavy and rich mulchings are annually given.—JOHN CRAWFORD, *Coldington Hall, Newark*.

Plums are at home here, doing remarkably well on the limestone formation, gritstone and toadstone (a volcanic formation). These and Cherries should be planted extensively, the climate suiting them. Rivers' Early Prolific and Early Orleans never fail. I see the Czar is extensively cultivated at the Chilwell Nursery as a suitable Plum for this district. Old trees of white Magnum Bonum, Victoria and Coe's Golden Drop carry very fine, highly coloured and flavoured fruit, the last being delicious and the best dessert variety. Goliath is a grand Plum, and when well finished is very striking. Angelina Burdett always fruits and is very distinct in flavour. Green Gage scarcely ever finishes up of full flavour; a late district may have to do with it. I am anxiously waiting to hear more about Japanese Plums. I have a tree from America sent by a friend and which I hope to fruit next year.—GEORGE BOLAS, *The Gardens, Hopton Hall, Wirksworth, Derbyshire*.

The area of Plum plantations has trebled during the past five years, for the Plum grown as an orchard tree is a profitable crop generally. The trees flourish amazingly on the heavy, strong, deep loam of the Pershore and Evesham districts, giving early returns. The worst feature is, in a season like this the markets get overdone, and prices accordingly rule low. Pershore Egg Plum and Victoria are the chief sorts grown as orchard trees, with Gooseberry bushes underneath. The Gooseberries are picked green and marketed early. New kinds of Plums are not yet proven, except Rivers' Early Prolific. The Czar also promises well. Cox's Emperor, Pond's Seedling, and Belle de Louvain have been planted largely on account of their handsome size and consequent market value. The higher quality dessert Plums are shy bearers grown as orchard trees, but in sheltered places a few Golden Gage, Bryanston Gage, Kirke's, Black Diamond, and others are found to answer. I grow upwards of thirty varieties, and the best flavoured are Coe's Golden Drop, Old Green Gage, Denniston's, Jefferson, Nectarine, Transparent Gage, Oullin's, and Reine Claude de Bavay for late use are the best.—W. CRUMP, *Madresfield Court*.

I think there is no doubt the Plum would pay in most districts planted in orchards, provided good sorts were used, strong growers and such kinds as are most suitable for market being preferred. As regards soil, the Plum is not particular so long as it is not bog or too sandy; any loam suits them, a calcareous loam the best of any soil. Most of our trees here are old varieties, but among the newer ones, Belgian Purple, Grand Duke, Sultan, The Czar, and Monarch appear likely to do well. For flavour, Green, Purple, Transparent, and Bryanston Gages, Coe's Golden Drop, Jefferson, Reine Claude de Bavay, Oullin's Golden Gage, and Kirke's Purple among dessert kinds are the best. Belgian Purple, Cox's Emperor, Diamond, Early Prolific, Goliath, Old Orleans, Wilmo's Orleans, Sultan, The Czar, Monarch, Pond's Seedling, and Grand Duke are the best cooking kinds. Victoria and Pershore are, perhaps, the most pro-

lific, and both good for kitchen use and preserving.—G. RINGHAM, *Wrotham Park, Barnet, N.*

Plums are rather extensively grown around here, and generally are carrying good crops. The Red Magnum Bonum is the greatest favourite for market, as it bears freely, is of good size, and the colour is brighter than that of the Victoria, which is also largely grown and does remarkably well. The standards bear most freely of these varieties. If orchards are to be made I would advise planting half-standards, as they do not feel the effects of being blown about the same as standards; as they grow they can very easily be trimmed up to the required height. Gooseberries, Currants, or Strawberries can with advantage be planted between the Plums until the latter shade them too much, when they can be taken out. I would not advise planting too largely of Plums, as there are already enormous quantities grown, and frequently they do not pay for gathering and marketing, although near large towns there is a great demand for fruit. In this neighbourhood prices generally are high. The following are the best dessert Plums here: Old Green Gage, Coe's Golden Drop, Kirke's, Jefferson, Transparent Gage, Bryanston Gage, Oullin's Golden Gage, and Denniston's Superb.—HERBERT NOBLE, *Ashton Court, Bristol*.

I think the Plum a most useful fruit, and should pay to grow as an orchard tree, as it succeeds in almost any soil, and in a fair season it bears good crops, and in many seasons most abundant crops. Plums like a good light loam, and a south or west aspect. The best kinds that I grow for dessert are Coe's Golden Drop, Green Gage, Denniston's Superb, Guthrie's Late Green, Ickworth Impératrice, July Gage, Jefferson, Kirke's, Purple Gage and Transparent Gage; for cooking, Kirke's, Pond's Seedling, Diamond, Victoria, Washington, White Magnum Bonum, Prince of Wales, Orleans, Smith's Early Orleans, Early Prolific, and Goliath.—W. M. SMYTHE, *The Gardens, Basing Park*.

The Plum is an excellent and profitable orchard tree, doing, so far as my experience has gone, very well on all sorts of soil, though soils of a sandy nature, or where sufficiently deep on chalk, are the best. Such varieties as Rivers' Early Prolific, Czar, Victoria, Pond's Seedling and Monarch, and Farleigh Prolific, and Prune Damsos prove amongst the most reliable croppers. It is unfortunate that we cannot find the highest flavour in the fruits on standard or orchard trees. Whilst these give excellent cooking Plums, the best flavoured varieties are more fitted for wall culture.—A. DEAN, *Kingston, Surrey*.

I consider the Plum should be grown very much more extensively as an orchard tree than it is. A good loam resting on clay suits the Plum admirably. The kinds I would advise for orchard planting are Victoria, Prince of Wales, Orleans, Green Gage, Rivers' Early Prolific, and Prune Damson. In my opinion the best flavoured Plums are Green Gage, Jefferson, and Coe's Golden Drop, the last not being grown nearly so largely as it deserves. It scarcely ever fails here planted on east and north walls, and I often keep good fruit till the end of November.—EDWIN BECKETT, *Aldenham House Garden, Elstree*.

Respecting the cultivation of Plums, I have grown them equally well on heavy, medium, and light soils, but I prefer a good loam on chalk or limestone to any other, and unless a good market can be found so that any large quantity can be dried or made into jam, I would in no case advocate extensive plantations, for well do I remember several abundant crops that proved worthless as far as profit goes, with the exception of Green Gage, which always is much sought after. Were I inclined to grow extensively I should select very early and late kinds, as a glut of medium season varieties can generally be depended on. The kinds I have found to suit me best are Early Rivers, a good first early that should be in the most select collection, being prolific and a sure bearer. Green Gage I need not speak of. Jefferson is one of the finest Plums that can be found, both as a dessert and cooking sort, a splendid cropper. This has always been my favourite with

the exception of Golden Drop. Oullin's Golden is also another most desirable kind, and one that should not be left out of the first dozen. The same can be said of Transparent Gage, in every way a charming and distinct variety. Prince of Wales is another that has proved with me to be excellent. Victoria, the most useful and prolific of Plums, needs no comment from me, as it is a universal favourite. Ickworth Impératrice is a very late and excellent kind, and should be extensively grown. If on a north or east wall this can be had very late and good even in November. Kirke's carries a fine bloom, and is perhaps the handsomest of the blue kinds; it is a good bearer and of excellent quality. Prince Englebert is also a great favourite of mine, and should not be omitted from any collection. The same must be said of Pond's Seedling.—CHAS. LOTT, *Caversham Park, Reading.*

## ORCHIDS.

### MASDEVALLIA TOVARENSIS.

THE majority of pure white-flowered Orchids are high in price and rare, and consequently beyond the means of many cultivators. Of ordinary species, of which the type is obtainable for a few shillings, a white form when it turns up is often worth many more pounds. The flowers of the species named above are of the purest white and as beautiful as those of many rare and expensive kinds. Fortunately, the price brings it within the reach of all. It is, moreover, very free-flowering, and the blossoms last well in good condition. The flower-scapes attain a height of about 6 inches, and each bears from two to four flowers. The leaves are light green, erect, and not quite so long as the spikes. Like all in this genus, *M. tovarensis* delights in a cool and moist atmosphere while growing, and during the summer months requires to be very closely shaded, both on account of the foliage and also to keep the temperature sufficiently low. It delights also in a constant supply of fresh air, and the ventilators should at the season mentioned be always open day and night. This constant rush of air, of course, quickly dries up all the atmospheric moisture, and the syringe must be very freely plied about the stages and between the pots. For this reason partly the pots containing the plants are usually raised upon others inverted, otherwise in damping, the compost would be splashed with water each time and it would be difficult to decide whether or not the plants are dry at the root. Generally, when the weather is very hot and dry, the house in which the plants are growing will need damping as many as half a dozen times a day. In winter, too, this species and, indeed, all in the genus require more moisture in the atmosphere than any other Orchids. At this season *M. tovarensis* must have a little more heat than is usually given to *Odontoglots* of the coolest section, though if the temperature does not go below 50°—and this is not too high for the other kinds named—all of them may be easily managed in one house. The plants are sometimes moved into the Cattleya house, and this is better than allowing them to get too cool, but the comparatively dry atmosphere of this house is not suitable for them, or, at all events, only when in blossom. This Orchid never requires drying off at the root either in summer or winter, but during the latter season water must be very judiciously applied, as the roots are easily injured either by too little or too much. The appearance of the Sphagnum growing about the roots is the best guide to follow. This, when kept dry for any length of time, turns white

and feels hard and dead to the touch. For *Masdevallias* it should never reach this stage, but only enough water must be given to prevent this in winter. The most frequent cause of ill-health of *M. tovarensis* is over-burdening the roots with compost, this latter being often too close and heavy. Small pots thoroughly free from dirt and grit should be chosen, and filled at least two-thirds of their depth with clean potsherds, this being covered with a little moss. A little of the old material will be retained about the roots, and this will then usually bring the base of the leaf-stems a trifle above the rims. If it does not, a few more crocks or small charcoal should be placed under them sufficient to raise them to the height desired. Have ready clean Sphagnum and good peat fibre in equal proportions, and wrap a little round the roots. Mix in a few bits of potsherd very finely broken and surface over with the peat and moss, only pressing this sufficiently to keep the plants free from rocking about. The early spring is the most suitable time to repot, as the roots are soon afterwards active and take readily to the new compost. Until this is the case give only enough water to keep the moss alive, but afterwards water freely. If kept free from insects the growth will be rapid, and late in autumn

*Masdevallia tovarensis.*

the spikes will push up. These continue to produce flowers several seasons in succession, so if the blossoms are not required for decoration they should not be removed. If the flowers are cut separately and wired it answers the same purpose, though of course when so treated they do not last so well. Taken all round, *M. tovarensis* is one of the most useful cool-house Orchids, and wherever white flowers are wanted in quantity a good number of plants should be grown, while the amateur with only very little space at command will find that it will repay a little care. As the specific name implies, it is a native of the neighbourhood of Tovar, in New Grenada, and as it was the first known of the large-flowering section of the genus, it was much prized and very expensive when introduced. It first flowered in England in 1865.

**Cattleya maxima.**—This species is very widely distributed naturally and is an extremely variable kind. I recently saw a nice piece of the short-bulbed, deeply-coloured form which had been imported as *C. Trianae*. The spike was carrying three flowers, each about 4½ inches across, of a very distinct purplish rose colour on the petals, the sepals and lip being much lighter, the latter being stained in the centre with orange,

and having deeply coloured stripes leading to the throat. It is an easily grown kind, thriving well in company with others of the labiata group in pots with peat and Moss. The typical *C. maxima* is an old plant in cultivation, having been discovered growing on rocks and trees in equatorial America by M. Hartweg in 1844.—R.

**Cypripedium Sallieri Hyeaenum.**—This is a pretty variety in the way of *C. insigne*. The whole flower has a decided yellow tinge, this being especially marked about the lip. The petals have the upper side deep yellow, like those of *C. villosum*, the lower portion having a few spots of purplish brown. The dorsal sepal has a broad margin of white with purple spots about the yellow base. The typical plant is supposed to be a natural hybrid between *C. insigne* and *C. villosum*, while this variety may possibly be the progeny of the former and *C. villosum aureum*, which it much resembles in colour.

**Odontoglossum lyroglossum.**—This pretty species is now in bloom and may be mentioned as one of the handsomest of the yellow flowering *Odontoglots*. In habit it resembles *O. luteo-purpureum*, and it has been suggested as a natural hybrid between this kind and *O. Pescatorei*. The sepals and petals are yellow blotched heavily with brown, the lip similar in ground colour, but without the spots, or only a few small ones. This is heavily fringed, and the whole flower is about 3½ inches across. *O. lyroglossum* thrives well in the cool house in small pots in peat and Moss and should not be dried off at any time.

**Oncidium Forbesi grandiflorum.**—This is a decided advance on the typical *O. Forbesi*; the flowers are very large, often 3 inches across, and highly coloured. The band or margin of yellow is much narrower than in the type, but the sepals and petals are of great substance, overlapping each other. The growth is not very vigorous, and the leaves are of a bronzy hue like those of *O. crispum*, which it somewhat resembles in habit. It should be grown on rafts or in shallow pans, and only a thin layer of compost is needed.

**Odontoglossum Sanderianum.**—In habit and general characteristics this peculiarly attractive species strongly resembles *O. navium*, but the flowers are quite distinct in colour. These are produced on rather densely-set racemes about a foot in length and each flower measures about 2 inches across. The sepals and petals are narrow, pale yellow, with many spots of reddish brown; the lip has a larger blotch in front and is lightly fringed at the edge. The plant is very easily grown, and should be suspended in small pans or pots near the roof in the cool house. A free circulation of air is of the utmost importance, and therefore if the plants are hung near the ventilators, so much the better. Good drainage must be afforded by filling to within an inch of the rim with crocks, above this dibbling the compost firmly about the roots. Good peat fibre, chopped Sphagnum and finely broken crocks are all that is needed to grow it well. After potting, the plants require only enough water to keep the Moss alive, but as the roots begin to run freely more must be given, and at no time must the plants be dried off. *O. Sanderianum* is a native of New Grenada, and was introduced in 1881. The flowers are sweetly scented and last several weeks in good condition if kept dry.

**Oncidium Jonesianum.**—This very distinct-looking *Oncidium* is flowering freely, the sunny weather experienced during the early autumn having apparently suited it. The pseudo-bulbs of this kind are very small, the leaves constituting the chief part of the plant. These are about 1 foot in length, rush-like, channelled and deep green. From the base of the newly-formed growth the flower-spikes proceed, and each carries on strong plants upwards of a dozen flowers, each about 2 inches across. The sepals and petals are yellow with brown spots, and the broad spreading portion of the lip is pure white. *O. Jonesianum* delights in abundance of heat and ample moisture, and should only be lightly shaded during hot weather. It dislikes much compost about its

roots, and many growers are in the habit of growing it on blocks of cork or wood. This treatment involves so much trouble in watering, that it is hardly advisable. A good plan is to wire the plants to blocks and sink these in pots in crocks and a surfacing of Moss, placing the pots on a shelf near the glass and watering them almost daily in hot weather. This ensures a moist atmosphere about the roots which is almost impossible on the bare blocks. *O. Jonesianum* is a native of Paraguay, having been introduced from there in 1883.

### CYMBIDIUM GIGANTEUM.

ALTHOUGH closely resembling *C. Lowianum* in growth, this is quite distinct and perhaps preferable to it in the flowers. They usually commence to show the flower-spikes about the same time, but those of *C. giganteum* come much quicker to perfection, not, however, lasting so long in good condition. The flowers are large, and produced on rather stiff-looking spikes from the base of the pseudo-bulbs. The sepals and petals are yellowish, suffused with reddish brown, and have also streaks of purple. The lip is yellow and brown with crimson spots and blotches. *C. giganteum* has been described as of a shy-flowering habit, but with me it is a very free and constant bloomer. It is very easily grown and not fastidious as to temperature. Some growers prefer the cool house for this and *C. Lowianum*, and in a letter before me from a friend who grows them well he says that he has so dealt with all his plants. But wherever they are grown they require a substantial compost. Good fibrous peat, loam, and chopped Sphagnum in equal proportions, with a liberal addition of charcoal and potsherds, will grow them well, and an abundant supply of water is needed while growing. A few waterings with liquid manure during the time the spikes are forming are of assistance, this being made of cow manure and soot highly diluted or from any well-prepared artificial fertiliser. The plants root very freely, and consequently the compost soon becomes a network of the large fleshy roots, necessitating frequent repottings until they get too large for convenience, when they must either be broken up or more highly fed in order to ensure luxuriance of growth, without which the flower-spikes will be small and the blossoms poor. The plants are very subject to the attacks of a small brown or white scale, which clings to the foliage most tenaciously. It is often impossible to remove these in the ordinary way by sponging, so I usually have for the purpose a small stiff brush, or a pointed stick where this cannot be used. It is an Orchid which seldom gets out of order at the roots, and never if ordinary care is taken with the drainage and watering; but should this occur the plants should be shaken clear out of the soil and well washed in tepid water, afterwards repotting in a rather lighter mixture than recommended above and kept in a warm house for a time. *C. giganteum* is a native of Nepaul, and was discovered by Dr. Wallich, who introduced it to this country in 1837. H. R.

**Cypripedium Charlesworthi.**—This species is one of the most valuable additions made to cultivated Cypripediums in recent years. It was first exhibited a little over two years ago at the Drill Hall, Westminster, by Messrs. Charlesworth, Shuttleworth, and Co., and was then awarded a first-class certificate. Since that time, having been imported in considerable quantity, it has become quite a popular Orchid, as its beauty and distinctness certainly entitle it to be. In relation to other species of Cypripedium it most nearly approaches *C. insigne* and *C. Spicerianum*, although, of course, it is perfectly distinct from both, as well as more attractive. The feature of the flower, as in those two species, is the upper sepal. This measures  $2\frac{1}{2}$  inches to 3 inches across, and is almost orbicular in outline; the ground colour is whitish, tinged with rosy purple, and traversed by darker-coloured veins.

The petals and lip are of less conspicuous beauty, but serve well to heighten the effect of the large upper sepal. They are of a brownish yellow, the petals being 2 inches long and the lip somewhat shorter. The staminode is of a pure china white, and being of exceptionally large size is a conspicuous feature of the flower. The leaves are strap-shaped and of rich lustrous green.

**Cattleya Bowringiana.**—Although of comparatively recent introduction, this has become a very popular plant, and is a decided acquisition to the genus. It is a healthy growing Orchid, and thrives well in pots in the usual peat and Moss mixture. The pseudo-bulbs are about 18 inches high, and from between the two apical leaves the flower-spikes spring, bearing on strong plants upwards of a dozen flowers on each. These are individually about 3 inches across, the colour being bright rosy purple with a white throat. The ordinary Cattleya house routine suits it well, but the leaves are apt to become infested with thrips, which must be kept under if good results are looked for. It is a native of Honduras, and was introduced in 1884.

**Cirrhopetalum Medusæ.**—All the Cirrhopetalas are more or less remarkable in the structure of their flowers, but in none of them does this character become so striking as in *C. Medusæ*. This species—of which a good specimen is flowering now at Kew—is a native of the Malacca Straits. It was introduced about 1840, but owing to its never having been imported except in a haphazard way along with other Orchids, it is a comparatively uncommon plant. It is an epiphyte, with ovoid, angled pseudo-bulbs, which carry a single leaf of very hard, leathery texture and about 6 inches long. The flowers are crowded in a dense umbellate cluster at the top of a slender, erect scape. They are small, but remarkable for the extreme attenuation of the sepals. These at the base are one-eighth of an inch to a quarter of an inch across, but taper thence into thin, pendent tails 4 inches to 5 inches long, giving to the inflorescence, as Lindley said, “the appearance of a head of long dishevelled hair.” The sepals are creamy white, speckled with pink; the petals and lip are yellow, but small and inconspicuous. The species is not only pretty and interesting, it has the additional recommendation of being easily cultivated and a robust grower. Coming from the Malayo region, it is naturally a stove plant and moisture loving. It is best grown in baskets, in a compost of peat fibre and Sphagnum. It should be rested by withholding water during the winter season, giving sufficient, however, to keep leaves and pseudo-bulbs plump.

## FLOWER GARDEN.

### FLOWERS IN LONDON.

Ah! wad some power the giftie gi' us  
To see oursel as ithers see us.—BURNS.

IN writing on Trafalgar Square in THE GARDEN some few weeks ago I stated that London had for centuries been a place of gardens, and that it was fresher and greener and possessed of more flowers to-day than perhaps ever before. It is a long time since King Henry VIII. and his court “roade a-maying from Greenwich to the top of Shooter's Hill” (in 1515), and it is also a long time since “the tall may-pole once o'erlooked the Strand,” but even before these events the London citizens emulated each other in the care of their flowers and gardens. Nor were fruits neglected, since even Shakespeare makes one of his characters allude to the “good Strawberries” he had seen in the Bishop of Ely's garden, in the vicinity of the Holborn of to-day. History teems with incidental allusions to the old gardens of London Town, and it is pleasant to find that visitors from other shores are often struck by the profusion of our urban

squares and public gardens, and by the luxuriant growth of bright or fragrant flowers in the windows and balconies not only of the best houses in the best streets and squares, but also in the backyards, alleys, and stable-yards everywhere. Not alone is it a fashion in Belgravia or in May-fair, but in the crowded alleys and courts of the East-end you meet with windows bright and cheery filled with quaint old-world plants, with Toadflax and Saxifrage, Musk, red Cactus, partridge-breasted Aloes, or with stately old one-sided plants of scarlet Pelargoniums, or red and white Fuchsias laden with bloom. In no other city in the world is that personal form of decoration known as the “button-hole” such an institution as it is in London.

Best of all, however, are the now numerous open plots and open spaces, like the gardens along the Embankment, the gardens at Westminster, at the Temple, at St. Paul's Churchyard, with seats where the workers or visitors can rest, and watch the pigeons on the cool green grass, or hear a fountain splashing under the Plane trees, as in the old Temple Gardens. London may have been “a great wen,” “an excrescence on the fair face of Nature” in the long ago, though in reality we doubt it; but to-day, even if more sombre than Vienna and more smoky than Paris and noisier than Venice, it can still hold its own as one of the greatest and most beautiful cities in the world. This much seems to have been the impression it made recently on the editor of *Harper's Magazine*, who expresses himself as both surprised and charmed by the increase of pleasant amenities and of the enhanced agreeableness of London to-day as compared with London of a quarter of a century ago. He says:—

It is certainly a brighter and pleasanter city than it was twenty-five years ago, and it naturally follows that it is a healthier and happier place as well. Window-gardening has done as much as anything else to change the aspect of London. It has given the needed freshness and colour to the otherwise gloomy houses, and has transformed many of the streets into high-ways of beauty. London has also been cultivating its small parks and public gardens, and in almost every quarter the eye is cheered and pleased with greenery and with bloom. The great amount of life in the streets, and the gay apparel, with the flowers in the windows and the creepers on the walls, the bloom in arches and courts make of London in the summer the handsomest and most interesting city in the world.

After all, London is said to be the centre or focus spot of all that is best worth seeing and is most enjoyable. It is a beautiful new picture in a charming old frame. It is a compliment that we can all appreciate, this spontaneous notice of our gardening instincts, coming, as it does, from a literary man of such keen observation and unbiassed judgment; but we should have liked to have shown our visitor some of the historical gardens, not only in and near to London, but also throughout the country as well; the gardens at the Tower of London, at the Temple, at Lambeth Palace and at Hampton Court, or those at Hatfield (frequented by the Princess Elizabeth before she became Queen), or those at Burghley, near Stamford, where she visited her Lord Treasurer, the great Cecil, and laughingly told him that her money and his own brains had made it one of the most beautiful places in England. We could have shown him Chatsworth and Haddon Hall and Belvoir Castle, or the fine gardens in the Dukeries, such as Welbeck and Thoresby, Colwick Hall (where Lord Byron's Mary Chaworth lived as Mrs. Musters), Newstead Abbey, and a passing glance could have been had of Kenilworth and Warwick Castles, and we could have

inhaled the summer freshness of Rosemary, Lavender and Golden Thyme in what was once Anne Hathaway's garden at Shottery village, near Stratford-on-Avon. Then there are all the regal gardens of the south and those of the north country, that shed such a lustre on British gardening. But at all events we must rest and be thankful, and feel grateful to Mr. Howells for his appreciative article on England and her improved and improving institutions from which the above extract as to London gardens and their flowers was taken.

F. W. BURBIDGE.

**New Water Lilies.**—The new Water Lilies are thriving well in the lake at Didlington Hall, Norfolk. They are planted out in the lake near to the

#### LILIUM LONGIFLORUM IN SURREY.

THIS Lily, which is imported into England every season in large quantities from Japan, is grown in the gardens at Great Tangley Manor, near Guildford, in a large tract of open ground planted with dwarf Azalea mollis and Heaths in light alluvial soil mixed with a little peat. The bulbs are placed among the low bushes of Azalea and the Heaths, which give them the requisite protection against the cold winds of the spring, and at a slightly higher level just above the Azalea garden is a large sheet of water, from which irrigation is easy in dry weather. At Tangley these Lilies are found to be the hardiest of garden flowers, requiring no protection during the winter and blooming

in these quantities, the flowering season is prolonged over a month or six weeks. The bulbs, which generally reach this country in the finest condition packed in the yellow soil of Japan, deteriorate after a time, and should be renewed to some extent every year, but they can be had in lots of from one hundred to two hundred at many of the London auction sales during the season at very moderate prices if bought wholesale in the cases in which they arrive from Japan.

W. F.

**The Belladonna Lily in Norfolk.**—It is a common idea that this lovely hardy bulb must be placed under a wall adjoining a warm house. Again, many people are under the impression that it can only be grown in the south and west. I am fully aware in

*Lilium longiflorum* in Surrey. From a photograph by Mr. W. Flower, Great Tangley Manor, Guildford.

mansion in water from 12 inches to 18 inches deep and I was told they had bloomed abundantly during the summer.—J. CROOK.

**Schizostylis coccinea.**—I was pleased to see Mr. Day's useful note (page 330) on this good old plant. One seldom sees it. A gardener under whom I served used to grow a quantity of it on a west border, the plants being lifted with as much soil as possible in October and planted in boxes and pans, being then removed to a cold vinery or Peach house and placed in a light position. Here they afforded a long succession of their brilliant spikes for a considerable period. They proved most useful for cutting, and lasted a good time if given a change of water. Scarlet flowers are none too plentiful at this date, and it would, I am sure, pay all who need variety in cut bloom to get a stock of *Schizostylis coccinea* and treat in the way described. Replanting may be done in March in light loamy soil, adding a little leaf-mould.—J. C.

profusely in July and August, most of them bearing two or more flowers, very many of them five or six, and some as many as eight on a single stem. They grow from 2 feet to 3 feet high, and some higher. The leaves are a beautiful shining green, the flowers in nearly all cases absolutely perfect both in form and colour—the purest white. While other Lilies are much subject to disease and can hardly be depended on to flower any two years alike, it is seldom that any disease attacks the longiflorum Lily. At Tangley there is certainly no plant that bears the same almost invariable appearance of perfect health and strength. Last year there were probably as many as from 1500 to 2000 of these Lilies in flower at one time—one group of about five hundred, others of from one hundred to two hundred, and others in smaller groups of from ten to fifteen. Grown

Cornwall and Devonshire it does magnificently. For several years this Lily has bloomed most satisfactorily in the kitchen garden at Didlington Hall, Norfolk, on a south border from 8 feet to 12 feet from the wall. I am told it never receives the least protection. The stems were strong and the blooms large. The soil is of a light sandy nature and very dry.—J. CROOK.

**Delphinium flowering twice in one season** (*S.*, p. 310).—There is nothing unusual in the Delphiniums pushing up a second crop of flowering stems in the same year. Indeed, this may be accomplished even in ordinary seasons with many kinds, provided the plants have been planted one whole year. The only thing to be done is to cut the flower-spike clean away as soon as the flowers fade, when the strongest of the clumps will quickly push away into new growth, and many will bloom in the ensuing autumn. The old spike must be cut away close to the soil, say to within 4 inches of it. Much the same remark applies to the single and double *Pyrothrums*.

Where a collection of either of these is grown, a second crop of flowers is always welcome, as they come at a time when such things are by no means plentiful. Of the Pyrethrums I have had flowers equally good in autumn as in early summer. The second spikes of Delphiniums usually attain to about half the height of the first ones, but are decidedly welcome notwithstanding.—E. J.

### FLOWER GARDEN NOTES.

**MULCHING.**—The weather of February, 1895, which crippled, and in some cases destroyed things that commonly rank as hardy plants, points to the advisability of carrying out surface-mulching to a much greater extent than has hitherto been the case, and as the glass already drops below freezing point with a persistency that is rather uncommon thus early in the winter, the mulching may well be performed at once before the frost has a chance to penetrate deeply into the ground. Partially decayed leaves answer the purpose of a mulch fairly well, but are only admissible in sheltered situations. As this material dries quickly in the open, and with the first high wind is apt to be blown in all directions, a better material is found in that obtained from a heap that has been built up of stable litter, garden refuse and leaves, and allowed to heat sufficiently to kill insects without getting dry to an extent that will destroy its nutritive properties. Among the plants to be treated are the tuberous and fibrous-rooted *Tropeolums*, also beds that having been clothed during the summer with the Canary Creeper are to be similarly treated another season and are not to be filled during the winter. In the case of the annual this mulching is essential to the preservation of the seed and the young seedlings that will come up thickly another season if the frost is kept out of the ground. Such seedlings are more robust and come more quickly into flower than those turned out of pots from seed sown in early spring. Nearly the same remarks, so far as preservation for another season is concerned, hold good respecting the Sweet Tobacco. This is sometimes used, it may be accidentally, in a situation in which it is seen to great advantage, hiding a bit of unsightly wall, for instance, or perhaps facing a row of evergreen shrubs or young conifers, and its perpetuation by root-propagation can be ensured by the aid of a substantial mulch. Although in the early season appearances seemed to indicate that the clumps of outdoor Fuchsias were destroyed, they have come up again and have grown and flowered well, although the size of the clumps has been considerably lessened. It will be well to mulch these as soon as the growth is cut back, also *Montbretias*, *Gypsophila*, *Lobelia cardinalis* and *L. fulgens*, and indeed anything that suffered in the slightest degree last winter. Though this was an exceptional experience, we may get the like again, and a little attention at the present time may save a considerable amount of replanting another spring.

**PLANTS FOR DRY BORDERS.**—The folly of planting the common summer-bedding plants in dry poor spots where they can receive little after-attention was again apparent in the summer of 1895, and in one or two instances where such planting was made I noticed the things presented a singularly pitiable appearance. It should be widely known that there are many herbaceous plants that will do fairly well in such situations, and all of them that will stand the winter well should be planted as soon as possible, that they may get a good hold of the ground before the advent of frosty weather. Where practicable, and if time permits, the border prior to planting may be enriched and made more retentive of moisture by the addition of a compost (if none other is available) from a heap of fairly leamy road sidings to which a liberal dose of cow manure has been added. Among the plants likely to do well will be the gold and silver *Thymes*, the alpine *Phloxes*, *Iberises*, the hardy *Silenes*, the silvery *Veronica* and *Santolina*; and among taller things, *Saponaria splendissima*, *Nepeta Mussini*, the *Megaseas*, some of the *Lychnis*, *Linarias*, *Eryngiums*

and *Centaureas*. If a dwarfier carpet is considered advisable between the groups of different species, it may be formed of hardy *Sedums* and the double *Chamomile*, the latter to be allowed to flower, or not, as may be required. The mulching advocated in the case of ordinary herbaceous borders and for somewhat tender plants is absolutely essential in the case of dry, sloping ground, and should be put on immediately after planting.

**POLYANTHUS.**—If there is one hardy spring-flowering plant used largely in the flower garden that has come very prominently to the fore of late years it is the *Polyanthus* family, and the many different shades of colour available enable the flower gardener to make an excellent display with this family alone. Thus, if one can pick out, say, half a dozen distinct shades, beds can be filled respectively with them, or they can be mixed together; also, if batches of the true *Polyanthus* type and the *Primrose-Polyanthus* are grown separately as seedlings, they may either be mixed at planting to give a broken surface to the bed, or the one may be used as a centre block and the other as an edging. If there are any specialities among the old stock that it is desirable to increase by division, the operation may be performed at any time. Still following up the question of mulching (with which these notes were started), I may mention that all members of the *Polyanthus* family are immensely benefited by it in all light dry soils. They will succeed fairly well in such soils always provided the roots are kept somewhat cool—a state of things in exposed situations and with a hot spring that is only effected by the aid of a heavy surface-mulching. The improvements in the size and shape of flower have been very marked within the last few years, especially in the purple and crimson shades, and some very beautiful varieties are annually obtained from a packet of good seed.

**AUTUMN TINTS.**—Although a continuation of frost has been responsible for the destruction of the flowers, and only batches of *Scabious* and *Starworts* that receive nightly protection are still available, the decaying foliage of tree, shrub, and flower is beautiful in its way and helps to make an attractive picture. I have noticed specially this autumn the marked difference in the prolongation of the decay and the partial or rapid assumption of the autumnal tint. Again, whilst one tree or shrub is beautiful in its decay right away to the final falling of the leaf, in others the foliage in its last stage presents a very dingy, dirty appearance, a remark applicable to both native and exotic trees. Two exotic trees close together in our grounds represent the earliest and latest stage of leaf shedding; these are *Gymnocladus canadensis* and *Taxodium distichum*. Two others not far apart, viz., *Ginkgo biloba* and *Laurus sassafras*, are noticeable for the different effect produced on the foliage by frost. In the one case the tree was completely stripped in a few hours; in the other, the foliage, although browned, still hangs tightly. The hardy *Azaleas* are almost as beautiful in their autumn dress as when clothed with flower, and in their case the prolongation of autumn tints where the plants are sheltered is very marked. One of the brightest bits of colour at the present time is furnished by a bed of these *Azaleas* that, having become somewhat drawn and leggy, were pegged down last spring to within 18 inches of the ground, thereby transforming the bed, before somewhat patchy and showing many gaps, into a dense mass of foliage. The only drawback to the arrangement at present is the somewhat formal appearance, but that will be altered another season, some shoots naturally growing away from the rest and standing well above them. E. BURRELL.

Claremont.

**Bouvardias for the flower garden.**—So far as I have seen, only a few of the gardeners in the west of England use *Bouvardias* in the flower garden. There may be good reasons for this, as it is probable that they would prove of little value in a less favoured climate; but where they will bear the exposure, I do not know any plant that

gives less trouble after a stock is obtained, or one that makes a choicer, brighter bed over a longer time than the single form of Hogarth. I saw a bed at the end of September in Mrs. Hancock's garden at Hulse, near Taunton, the plants bristling with clusters of flowers. I was told the plants were in the same condition when set out early in June, and all through the summer they had made a still better display. The habit of growth of this *Bouvardia* makes it suitable for filling flower beds where a bright subject is required, and at the same time an absence of unruly growth desirable. Only those who have seen the plant so treated can realise the freedom with which it flowers or the length of time it continues in that condition. This will be better understood, perhaps, if I briefly describe the way in which the plants are treated. The first year four or five plants are put into 4½-inch pots and grown in a cold frame. In the following winter they are pruned rather hard, and are then shifted into 6-inch and 7-inch pots, according to their strength. In the spring they are placed in a cold pit, where they remain until it is safe to risk them in the open air. In May the pots are plunged just below their rims in the soil, and remain so until the autumn. Early in the following spring they are again pruned rather hard, quite half of the old soil is shaken away from the roots, and after being repotted they are returned to the cold pit again, to be treated as before. Some of the plants which I saw were seven and eight years old.—J. C. CLARKE, Taunton.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 12.

THERE was again at this meeting a perceptible falling off in the extent of the exhibits. Nevertheless, there was ample abundance of quality and variety to well repay one for a visit, much more so than in many competitive exhibitions with a considerable outlay of money in prizes.

*Chrysanthemums*, as a matter of course, formed a conspicuous feature, the one welcome fact above all others being the general departure from the orthodox show-boards for the arrangement of the blooms. These were chiefly shown with small fine-foliaged plants intermixed or upon longer stems with the foliage left upon them. In this way a capital display was made by Mr. Wythes, from Syon Gardens, he being about the first to adopt this plan. Another excellent arrangement came from Messrs. H. Cannell and Sons, and yet another from Mr. T. S. Ware. Some superb blooms of the fine yellow incurved Japanese *Thunberg*, still unsurpassed in its form and colour, came from Mrs. Crawford, Gatton, Reigate. Mme. Marie Hoste, from the same source, was of equally good quality. Winter-flowering *Geraniums* from Swanley were also a conspicuous feature, as were both *Canna Queen Charlotte* and the new giant Sweet Violet Princess of Wales, best described as a glorified *Zar*. The *Javanico-jasminiflorum* hybrid *Rhododendrons* from Chelsea exemplified in the best possible manner the value of these splendid varieties for this season of the year. *Orchids* were again a great feature, *Cattleya labiata* still being most prominent, and that in great variety. *C. aurea* was also shown in superb condition from Stand Hall. Some fine hybrid *Laelio-Cattleyas* and *Cypripediums* came from the Veitchian collection, and likewise from Mr. Ingram at Godalming. Of other *Orchids*, *Habenaria Susanna* is worthy of special note, a lovely example being shown from the St. Albans collection with no less than ten spikes. Of fruit there were several excellent collections, notably the grand examples of English-grown Smooth Cayenne Pine-apples from Frogmore and the splendid bunches of *Chasselas Napoleon Grape* from Mentmore, whence Mr. Smith brought three bunches perfect in colour and size of bunch and

berry. These were from a Vine grafted on the Muscat of Alexandria, and were ripe as long back as the first week in August last. It is almost needless to say that a cultural commendation was awarded. Apples and Pears in one hundred varieties came from Belvoir Castle Gardens, both colour and size being conspicuous. From Jersey came some superb fruits of Doyenné du Comice and other Pears, as well as some good-looking Apples. Vegetables were conspicuous by their absence on this occasion.

### Orchid Committee.

First-class certificates were given to the following:—

**CYPRIPEDIUM MARCHIONESS OF SALISBURY.**—A hybrid between *C. bellatulum* and *C. barbatum* superbum. Certificates have been awarded to plants from this particular cross on no less than three previous occasions, the varieties being *C. Charles Richman*, *C. Charles Richman* var. *Meteor*, and *C. Leysmanium*. The plant now certificated differed from those principally in its longer and somewhat more drooping petals, which are paler in colour and more evenly spotted with chocolate brown. The dorsal sepal is greenish white at the centre, tinted with rose towards the top, lined and spotted with chocolate brown; lip brownish purple, shading to greenish rose. From Messrs. F. Sander and Co.

**CYPRIPEDIUM MILO GRANDE.**—An extra large, finely-shaped flower, the result of crossing *C. insigne* Chantini with *C. cananthum* superbum. The dorsal sepal is greenish, thickly spotted with brown in the centre, the top having a broad white margin; the petals and lip dark brown. From Messrs. J. Veitch and Sons.

**LALIO-CATTLEYA CALLISTOGLOSSA IGNEESCENS.**—A cross between *Cattleya gigas* Sanderiana and *Lælia purpurata*. Sepals and petals rose, sepals dark crimson in front, having two distinct yellow blotches in front of the throat. The principal distinction from the original is the extra dark colouring on the lip. From Messrs. Veitch and Sons.

**LUDEMANNIA TRILOBA**, in which the sepals are bright yellow, tinted with brown, and the petals yellow, spotted brown. The three-lobed lip is bright lemon-yellow, the flower-scape pendulous, 3 feet long. From Sir. T. Lawrence, Bt.

Awards of merit were given to the following:—

**CATTLEYA LABIATA MISS CLARA MEASURES.**—Sepals and petals white; lip white, lined throughout the throat, and with a light blotch on the lip rose-purple. From Messrs. F. Sander and Co.

**CATTLEYA LADY INGRAM** (*Cattleya* Eldorado × *C. Dowiana aurea*).—The sepals and petals, creamy white, lip rose-pink lined with a deeper shade in front, having an orange-yellow throat. The plant, though small, the seed having been sown in 1888, carried three fine flowers, which are in the way of those of *Cattleya* Hon. Mrs. Astor. From Mr. C. Ingram.

**LALIO-CATTLEYA OTHELLO** (*C. maxima* × *L. elegans* Turneri).—The sepals and petals are bright rose, lip rose lined with crimson, margined with white. From Mr. C. Ingram.

**CATTLEYA CECILIA** (*C. Lawrenceana* × *C. Trianae*).—This in shape is like a *Cattleya Lawrenceana*; sepals and petals lilac, lip of the same colour, with a slight crimson blotch in centre. From Mr. C. Ingram.

**LALIO-CATTLEYA SEMIRAMIS** (*C. Gaskelliana* × *L. Perrini*).—The general character of the plant partakes largely of *L. Perrini*; sepals and petals rose-purple, lip lined and blotched with rosy purple. From Messrs. Veitch and Sons.

**CYPRIPEDIUM POLLETTIANUM** (Burford variety).—An extra fine form, the flower larger than in the original and showing more of the *cananthum* parent in the dorsal sepal. From Sir Trevor Lawrence.

Messrs. J. Veitch and Sons had a fine group, amongst which, besides those referred to above, were *Cypridium* Arthurianum, *C. Mimosa*, a fine variety of *C. Niobe*, *Epidendrum Wallisii-ciliolare*, *Cypridium Ianthe*, *Lælio-Cattleya Decia*, *Cattleya Dowiana aurea*, *Miltonia Moreliana*,

*Cypridium Phædra*, *Lælio-Cattleya Pallas*, *Cypridium cananthum superbum*, *Phalaenopsis Vesta*, *Cattleya O'Brieniana*, *C. Bowringiana*, *Zygopetalum Klabochozum* and *Cattleya leucoglossa* (silver Flora medal). A silver Banksian medal was awarded to Mr. T. Statter, Stand Hall, for a fine group of cut flowers, principally *Cattleyas*, including *C. Dowiana* in variety, several fine forms of *C. labiata* and *C. Bowringiana*. *Cypridium vexillarium*, *C. Edwardi* and various forms of *C. insigne montanum* were also shown here. Messrs. F. Sander and Co., St. Albans, sent a choice group, consisting of *Cypridium insigne montanum* in variety (showing the yellow and dark forms), *Cymbidium Winnianum*, *Celogyne fuscescens* (a fine plant with three spikes), *Sophrontis grandiflora*, a fine form of *Lycaste Skinneri*, *Habenaria Susanna* (a made-up specimen with ten fine spikes), *Calanthe Clive*, *Cattleya labiata* in variety (including Miss C. Measures), *Angraecum polystachyum*, *Dendrobium album*, *Trichopilia brevis* with two flowers, *Anæctochilus Petola*, and a new form called *Sanderianus*; also *Saccolabium acutifolium*, the flowers borne in clusters of twelve to eighteen. The sepals and petals are brown, lip white, with brown spots in centre. Messrs. B. S. Williams and Son received a silver Banksian medal for a small, but choice group, prominent amongst which were *Pescatorea Roezli rosea*, *P. Klabochozum superba*, *Cypridium Harrisianum superbum*, *C. Pitcherianum* (Williams' var.), *C. Adonis superbum*, *C. insigne Wallisi*, *Miltonia Roezli* and *Celogyne Gardneriana*, an old species with pendulous spikes of white flowers. Mr. F. W. Moore, Glasnevin, sent *Phalaenopsis denticulata*, the flowers creamy white, barred with brown; *Spathoglottis pubescens*, a small yellow-flowered species in the way of *S. Fortunei*, and *Eriopsis rutidobulbon*. Mr. Measures, Cambridge Lodge, Camberwell, sent *Cypridium Olenus*, *Masdevallia abbreviata* (like a white form of *M. polysticta*), *Pleurothallis longissima*, in the way of *P. rubens*, but with larger flowers and longer spikes than that species. Mr. J. Gurney Fowler sent a spike of the rare *Cymbidium Traceyanum*, carrying twelve fine flowers.

### Floral Committee.

A first-class certificate was given to—

**DRACENA LATIFOLIA**, a handsome broad-leaved kind, which will be much valued for the conservatory. Its leaves are of great texture, nearly a yard long, arching outwards and prettily undulated on the margins. They are of a deep shining green colour, distinctly edged with a lighter, almost white tint. Plants of various sizes were shown. It came from Mr. W. Lamb, gardener to Mr. H. O'Hagan, River House, Hampton Court.

Awards of merit were given to—

**CHRYSANTHEMUM CLINTON CHALFANT.**—A reflexed yellow-flowered variety of American origin, and an acquisition by reason of its great decorative qualities. The flowers are not too large, but in colour are very rich and clear. A plant was also shown about 4 feet high carrying a dozen or more flowers. It was shown by Mr. W. J. Godfrey, Exmouth, Devon.

**CHRYSANTHEMUM ANNIE HEARD.**—A single-flowered kind, free and graceful, bearing many-flowered sprays, the blooms not large, but broad-petalled and of a pure white colour. This also came from Mr. Godfrey.

**CHRYSANTHEMUM ARONA.**—This is a handsome incurved Japanese, large and full, and in some degree resembling Col. W. B. Smith, especially in colour, which is deep buff-yellow, glowing with a brighter tint towards the base of the petals. It was shown by Mr. H. Briscoe-Ironside, Burgess Hill, Sussex.

**CHRYSANTHEMUM OCEANA.**—An incurved Japanese, bold, but not coarse, with broad petals, and of a clear, soft canary-yellow colour, shading to a deeper lemon-yellow. Shown by Messrs. H. Cannell and Sons.

**CHRYSANTHEMUM VICAR OF BRAY.**—An English seedling of the Japanese class, with a graceful reflexing form, the petals curling and intermingling

prettily. It is of a rich bronzy buff colour, orange shaded in the centre, and with fawn-yellow reverse. It was shown by Mr. R. Owen, Maidenhead.

**CHRYSANTHEMUM ROBIN ADAIR.**—This is of the Anemone-flowered type, large and shapely, the centre florets lilac-pink, shaded with yellow, the ray petals blush-white, flushed with lilac, more especially on the reverse. Also from Mr. R. Owen.

**CHRYSANTHEMUM MRS. R. C. KINGSTON.**—This belongs to the true incurved class, and has a very large, high, shapely flower, the reverse of the petals being a deep lilac-rose, but inside they are of a clear blush shade. This also came from Mr. R. Owen.

**RHODODENDRON NUMA.**—This is a fine hybrid of complex parentage, but partaking of the *R. javanicum* character, and a welcome addition to the ever-flowering family of greenhouse Rhododendrons. Its habit of growth is good, and the flowers are of a rich telling shade of orange-red, shading towards crimson in the tube. Shown by Messrs. J. Veitch and Sons, Chelsea.

**PENTSTEMON COBEEA.**—Several fine plants of this handsome species, which comes from Texas, were shown. It has large, broad, deep green leaves arranged all up the stem in opposite pairs. The flowers in size, shape and disposition resemble those of the best garden kinds of the present day. They are of a pale mauve colour, streaked with a deeper tint in the throat and shading to white in the lobed petals. It was shown by Mr. Bain, gardener to Sir Trevor Lawrence.

**POLYSTICHUM CONSTRUCTUM.**—A distinct hardy Fern, the result of crossing *P. aculeatum* and *P. angulare*. It has narrow, tapering, erect fronds of a deep olive-green colour, arranged somewhat regularly around the central cone. It was shown by Mr. W. Marshall, Auchinraith, Bexley.

From Messrs. H. Cannell and Sons came a large collection of Chrysanthemums in show, single and decorative varieties. M. P. Dewolfs, yellow; T. Wilkins, buff; Reine d'Angleterre, rose; Sir E. T. Smith, yellow; Oceana, yellow, with bold, broad petals; Duke of York, and Philadelphia were the finest Japanese kinds. The thread-petalled varieties were represented by some charming kinds, notably Mrs. Filkins, yellow; Silk Twist, white, tipped with pink; Centaurea, yellow, and Piper Heidseick, white. Single Pelargoniums also from Swanley were brilliant, rather formally bunched, but prettily arranged on a groundwork of Maiden hair Fern. Enid, soft red; Delicatum, mauve-pink; Donald Beaton, scarlet; Duke of York, dark crimson; Mrs. Hall, salmon; Snow-drop, white; Rev. Bartram, crimson; Lord Farrer, light red, and St. Cecilia, rich salmon, represent a good selection from a lovely lot. This exhibit was a welcome one, well showing that the Chrysanthemum is not the only fine flower of the present time. It would be well to moderate the Chrysanthemum craze and give more attention to zonal Pelargoniums for winter flowering. A silver-gilt Banksian medal was awarded. Mr. G. Wythes, gardener to Earl Percy, Syon House, showed eighty varieties of cut Chrysanthemums arranged in a charming, graceful way, the flowers on long stems rising out of a bed of Maiden-hair Fern. Among the best flowers we noted Hairy Wonder, Éda Praes, Vivand Morel, W. H. Coles, Florence Davis, G. C. Schwabe, W. Seward, Robert Owen, Mme. Darrier, D. B. Crane, with Jane and Miss Mary Anderson, two of the most charming single-flowered varieties to grow for cutting. A silver Banksian medal was awarded. Mr. T. S. Ware showed Chrysanthemums in quantity, chiefly cut blooms, well arranged with Crotons, Ferns, and Grasses. The best flowers were those of Rose Wynne, Mme. Rozain, Golden Gate, Niveum, Amiral Avellan, and A. H. Fewkes, the last a deep rich yellow incurved. The award was a silver Banksian medal. Mr. Pentney, gardener to Mrs. Howard, Isleworth, received a bronze Banksian medal for a little group of cut Chrysanthemums prettily arranged with Asparagus and Ferns. Mr. W. J. Godfrey, Exmouth, who was

awarded a silver Banksian medal, showed several of the newer varieties of Chrysanthemums finely, notably Reine d'Angleterre, Wilson Addison, Mrs. G. West, A. D. Chattin, Cecil Wray, King of Yellows, a large incurved yellow, and Mrs. Hume Long, rose amaranth, long-petalled, partially quilled; Mr. W. J. Godfrey, white and hairy; and Clinton Chalfant, reflexed yellow, described above. Mr. R. Owen sent several new kinds, as Robin Adair, Mrs. R. C. Kingston, Vicar of Bray, already described, and G. Haigh, rosy buff. A beautiful sport from R. Petfield; John Lightfoot, blush white, edged with lilac, and others. A bronze Banksian medal was awarded Mrs. Jones, Greenford Place, Sudbury (gardener, Mr. Jones), for a group of fifteen varieties of single-flowered Chrysanthemums—Jane, white; Mary Anderson, blush; Rev. Henfrey, amaranth-crimson; Princess May, dark crimson; Jane Wells, lilac-pink; Purity, white; and Edwin Weller, pale buff, being the best. Mr. Goble, Walcot Nursery, Isle of Wight, showed six plants of a dwarf, free-blooming, single white-flowered Chrysanthemum named Ewan Cameron. Plants and cut flowers of Chrysanthemum Philadelphia were shown by Messrs. B. S. Williams and Son, but the committee passed the variety, and its comparative failure in the hands of all who have had it proves the necessity of an independent trial before making a high award to an unknown, untried novelty. Mr. Slogrove (gardener to Mrs. Crawford, Gattton, Reigate) exhibited two very fine stands, each of a dozen grand blooms of Chrysanthemum Thunberg and C. Mlle. Marie Hoste. Mr. H. Briscoe-Ironside also showed a pretty series of new varieties; and from Mr. Owen Thomas, Royal Gardens, Frogmore, came a plant over 6 feet high of Princess Ena, a pretty hairy kind of a distinct pink colour, which received an award of merit last year. Messrs. J. Veitch and Sons showed a charming selection of their Rhododendron javanicum forms, also the original species and earlier hybrids, thus showing the marked advance that has been made. Some of the best were Primrose, yellow, pure in colour and very fine in flower; Taylori, rich pink; Ruby, deep red; Ajax, light red; and Maiden's Blush.

#### Fruit Committee.

The exhibits before this committee, though less numerous than at previous meetings, were notable for their excellence, the Pine-apples from Frogmore and hardy fruit from Belvoir being very fine. From the Royal Gardens, Frogmore, Mr. O. Thomas sent eighteen very fine Smooth Cayenne Pines, all good and beautifully finished, with very small tops. This exhibit was much admired, and well merited the silver-gilt Knightian medal awarded. Mr. Divers, Belvoir Castle Gardens, Grantham, staged a very nice collection of Apples and Pears—100 dishes in all—the Pears being specially good. The fruits were staged with berries and foliage, thus adding to the effect. Mention must be made of such varieties as Blenheim Orange, Lady Henniker, King of the Pippins, Cockle Pippin, Bramley's Seedling, Bismarck, Beauty of Kent, Cox's Pomona, Peasegood's Nonsuch, Frogmore Prolific, and Annie Elizabeth, all notable for their colour and finish. The best Pears were Marie Louise, Winter Nelis, Beurré Rance, Beurré Sterckmans, Glou Morceau, Easter Beurré (very good), and Maréchal de la Cour (silver-gilt Banksian medal). Mr. H. Becker, Imperial Nurseries, Jersey, sent a smaller collection of fruit, including good dishes of Cox's Orange, King of the Pippins, Blenheim Orange, Winter Calville, Flower of Edinburgh, Scarlet Pearmain, with other well-known varieties. He also staged nice-looking fruits of Crimson Seedling, Scarlet Pippin and Golden Nonparoil Apples. Good Pears in twelve varieties were likewise sent (silver Banksian medal). Mr. Smith, Mentmore Gardens, Leighton Buzzard, sent three very fine bunches of Chasselas Napoleon Grape from Vines grafted on Muscat of Alexandria, the berries large, of a beautiful amber colour, perfect in shape and well flavoured. Messrs. Rivers and Son, Sawbridgeworth, Herts, sent Apples Rivers' St. Martin and Rivers' Codlin, nice-looking

fruits and of good quality. Messrs. Veitch, Chelsea, sent new Apples Welsh Beauty, Reinette de Damson and Fraise de Hoffinger, but the cropping qualities could not be judged from the single dishes sent, though the fruit promised well as regards appearance. Mr. L. E. Thomas, Berkhamsted, sent seedling Apple Eureka. Mr. Ray sent a seedling Apple named Ivanhoe. The Rev. J. R. Drummelow, Chard, sent bunches of Black Hamburg Grapes ripened out of doors and in excellent condition as to size and colour. Mr. McIndoe, Hutton Hall Gardens, Guisborough, Yorks, sent a new Pear, Charles Ernest, a nice-looking fruit. Mr. Thomas, Frogmore, sent a new Plum, Frogmore Late, a nice-looking black variety.

The lecture by Dr. M. T. Masters was on substitutes for Larch. He dealt briefly with the Larch disease, which it was found impossible to stamp out, and therefore he thought an efficient substitute should be found. The chief and first requisite was something cheap that quickly produced good timber. He found on looking through the lists there was plenty of substitutes, but there was a difficulty in finding sufficient stock of them in nurseries. He thought the Corsican Pine was the best substitute, using for comparison the table of values given in the conifer conference report, taking Scotch Fir as the standard. The Weymouth Pine, introduced to Longleat in 1709, was not found first-rate, but he believed Nordmann's Silver Fir was one of the very best timber trees we were likely to have, better even than the Silver Fir. As regards the Douglas Fir, it was not adapted for exposed positions, but altogether was a tree to be recommended, putting on timber very quickly. He would give it second place, as the quality of its wood left nothing to be desired. Almost equally good was Menzies' Spruce, which grows very fast, and there is a magnificent wood of it in Kent. The Redwood he would also recommend, and it was well adapted for coppice wood. Among newer things Lobb's Cypress was of the greatest promise for the future. Lawson's Cypress in America has the highest character as a timber tree, and he thought it would if grown thickly be a most efficient substitute for Larch. Even better would be the Nootka Sound Cypress, which is never likely to be hurt by cold. Abies brachyphylla from Japan would be found a good tree in the future, and there were many more worth growing, though less useful as timber trees. For seaside planting there was nothing better than Cupressus macrocarpa. The lecture was well received by a good audience and some discussion followed.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

THE floral committee of this society held a meeting at the Royal Aquarium on Monday last, when Mr. T. Bevan occupied the chair. Several good exhibits of single-flowering varieties were presented to the committee, some of which secured high honours—a comparative rarity in these days of big bloom worship. There was a large number of exhibitors, and the principal collections came from Messrs. Cannell and Sons, Mr. Godfrey, Mr. H. J. Jones, Mr. R. Owen, Mr. W. Wells, Mons. Ernest Calvat, Mr. Briscoe-Ironside, Mr. C. E. Shea, &c. First-class certificates were awarded to the following—

CHRYSANTHEMUM DOLLY.—A pretty little pom-pom commended by the committee last season. It is of reflexed form, with rather broad florets, colour deep yellow. It was raised and shown by Dr. Walker, of Wimbledon.

CHRYSANTHEMUM J. LIGHTFOOT.—A Japanese of medium size, florets notched and spreading, ground colour white, suffused and edged pale lilac. From Mr. R. Owen, of Maidenhead.

CHRYSANTHEMUM GEORGE HAIGH.—A sport from Robert Petfield; colour carmine-rose, shaded gold. Also from Mr. Owen.

CHRYSANTHEMUM MRS. H. WEEKS.—Six large blooms of this were staged. It is a Japanese with very broad florets, curly and intermingling,

building up a very deep massive flower; colour pure white, tinted blush. This was exhibited by Mr. H. Weeks.

CHRYSANTHEMUM MAJOR BONAFFON.—An incurved of pyramidal form, and having a mass of narrow pointed florets; colour a very pure pale yellow. Four exhibitors staged this variety, but the award was made to Mr. W. Mease, whose blooms were finest and deepest in build.

CHRYSANTHEMUM MRS. A. E. STUBBS.—A pretty single Japanese, with long, narrow pointed florets, centre yellow. From Mr. H. J. Jones, of Lewisham.

CHRYSANTHEMUM MRS. GEORGE WEST.—This, although a Japanese incurved, was almost as solid and regular as one of the old type. It is very large and the colour velvety amaranth inside, with a reverse of silvery pink. Another of Mr. H. J. Jones's varieties.

CHRYSANTHEMUM OCEANA.—A colonial seedling Japanese incurved of great promise. The florets are very broad, deeply grooved and heavily incurving. The colour is pure golden yellow of great purity. Shown by Messrs. H. Cannell and Sons.

CHRYSANTHEMUM ARONA.—Japanese with narrow pointed florets, somewhat incurving and pointed at the tips. The inside colour is reddish crimson or chestnut, and the reverse, wax-like golden yellow. A new seedling from Mr. Calvat called Vicomte René de Chezelles was almost identical in every respect; Arona, however, being presented first secured the award. Mr. Briscoe-Ironside was the exhibitor.

CHRYSANTHEMUM CLINTON CHALFANT.—An attractive reflexed Japanese of American origin, very pure yellow. Shown by Mr. Godfrey.

CHRYSANTHEMUM ANNIE HEARD.—A pretty little single, yellow centre, surrounded with short flat florets of pure white. This, too, came from Mr. Godfrey.

CHRYSANTHEMUM BARONNE DE BUFFIÈRES.—Japanese incurved, round and solid in form, florets of medium size; colour pale lilac, reverse pearly pink. From Mr. W. Wells.

CHRYSANTHEMUM M. CHENON DE LECHÉ.—A fine reflexed Japanese flower commended by the committee last year. Very long florets of medium width, colour primrose-yellow shaded salmon-bronze, outer florets shaded rosy bronze. Also from Mr. Wells.

CHRYSANTHEMUM Mlle. M. A. DE GALBERT.—A large white Japanese with long drooping florets. Another of Mr. Wells'.

CHRYSANTHEMUM LE MOUCHEROTTE.—A monster show bloom with long narrow florets, very full and double, a Japanese variety; colour pure yellow, tinted bronze. This, too, came from Mr. W. Wells.

CHRYSANTHEMUM EWAN CAMERON.—A single-flowered Japanese with flat florets, yellow centre. Shown by Mr. E. C. Goble.

There were many other noteworthy varieties—Harold Wells, a pale primrose incurved Japanese, being very fine; Australie, a large colonial-raised seedling, will be heard of again. Rêve d'Or, golden yellow, and Vicomte René de Chezelles were the finest in M. Calvat's exhibit, and are both very promising. Others, such as King of Yellows, Lady Ridgway, Mrs. C. Orchard and Mrs. Hume Long in the Japanese section, will no doubt be heard of again. The committee wished to see the following again: L'Améthiste, a rosy amaranth incurved; Wm. Bolia, a brightly-coloured Japanese of a somewhat similar shade; Duchess of Fife, large white Japanese incurved; Mrs. Hepper, white incurved; Mayor of Exmouth, Mrs. W. J. Godfrey and Harold Wells.

**The weather in West Herts.**—During the past week the weather has been very warm, wet, and windy. On each day the temperatures both during the daytime and at night have been above the average for the time of year. On two days the highest reading in shade exceeded 58°, while on three nights the exposed thermometer never fell lower than 45°. At 1 foot deep the tempera-

ture of the ground is at the present time about 1° in excess of the November average. Rain fell on each of the nine days ending the 10th to the aggregate depth of nearly 2½ inches. Since the beginning of the month over ten gallons of water have passed through the 2½ feet of soil in my percolation gauges, which are a yard square, thus showing how wet the soil has now become. On the 10th the wind towards night became very high, the mean velocity for the hour ending midnight amounting to thirty-one miles, and during some of the individual gusts it was blowing a "fresh gale"—direction south. On seven days this month no sunshine at all has been recorded, but the remaining days, on the other hand, have been tolerably bright for the time of year.—E. M., *Berkhamsted*.

## NOTES OF THE WEEK.

*Ipomœa ternata*, a South American climbing plant, has now some fine clusters of buds and blooms upon it in one of the plant stoves at Kew. The clusters of prominent inflated-looking buds give it a distinct appearance, and standing out conspicuously from their enlarged calyces, they expand into fine large blossoms of the purest white, the petals so thin as to be almost transparent. It twines about like the *Stephanotis*, but is deciduous.

*Cattleya labiata alba*.—Pure white forms of this late flowering *Cattleya* that combine shapely form and good breadth of petal with perfect purity of colour are not frequently met with. We saw one such in flower at St. Albans, the petals being of fine width, and there was not the faintest flush of any colour to tinge the spotless whiteness of either sepals, petals, or the front of the labellum. The tube of the flower inside was of a soft yellow, which rather added to the charms of the variety.

*Laportea morioides* (the Poison Tree of Queensland) may now be seen fruiting freely in one of the divisions of the T-range of houses at Kew. The plants here are comparatively small. They have each a single erect stem clothed with large heart-shaped leaves, whose surface is covered with bristly stinging hairs. The flowers are inconspicuous, but are succeeded by berries that look sufficiently tempting to induce one to try them. The fruits are like a small Mulberry, of a dull red colour, and borne in slightly branched clusters, each having about twenty.

*Tillandsia latifolia* is a brilliant and beautiful species, deserving more attention if we may judge from a group of it in one of the houses at St. Albans. The plants were planted out on a raised bed and they were most attractive both in leaf and bloom. The leaves are long and droop like those of *Yucca flaccida*. They are deep green, spotted all over their upper surfaces with a mealy whiteness. The flowers, borne in a long erect spike, which rises well up among the leaves, are of a bright vermilion-red hue, a colour welcome at one of the dullest periods of the year.

*Habenaria Susannæ*.—A grand white-flowered Orchid that will eventually be generally grown and regarded as one of the finest blooming plants of the dull season is this *Habenaria*. We saw a great quantity of it in flower in Messrs. Sander's nursery at St. Albans, and its effect in groups was superb, the bold erect spikes rising up from a leafy base and bearing long heads of blooms, the flowers quaintly formed and of snowy whiteness. In its striking aspect it may be best compared with the *Disa*, but its value for present blooming is great, and must give it a prominent place among Orchids.

*Begonia Rajah*.—This is one of the prettiest and certainly one of the most distinct among the many pretty leaved *Begonias*. It comes from the country about Singapore, and is being sent out by Messrs. Sander, of St. Albans, where we recently saw a quantity of it. It has a dwarf habit of growth and leaves like those of the *B.*

Rex varieties, but smaller. The colour is novel and exquisite, the main portion of the leaf being a deep bronzy green, much the same shade as pervades the leaves of Regner's Ivy at this time, and from this the venation stands out peculiarly prominent, the main veins being plainly delineated in a bright tone of yellowish green.

**Wyedale Plum.**—On October the 29th Mr. Wythes exhibited the above Plum in the collection of fruit staged by him at the Drill Hall meeting of the R.H.S. The Plums appeared in such a fresh, clean condition, that one would imagine they were only just ripe, proving the value of the variety as a late sort that will hang on the trees in good condition for a considerable time after the fruit is ripe. I have grown this variety in several counties, and always found it a moderate and continuous bearer, and one of the latest for use both for cooking and dessert. If it had been as large as some of our more showy Plums, it would ere this have been known in almost every garden of any extent, but as it is rather small in size, its merits have not been generally recognised.—W. G. C.

**Asparagus crispus** is the name under which Messrs. Sander grow in great quantity a lovely and graceful species that we have seen elsewhere as *A. decumbens*. It appears to be synonymous with the *A. Sprengeri* of Continental nurserymen. The trio of names is confusing, but it is important that all should know and grow this species. We have seen some fine plants of it in hanging baskets, notably in the conservatory at Warley Place, but in the St. Albans nursery a new use is found for it, namely, to drape the fronts of stages along with *Panicum variegatum*. In one instance the beauty of a lot of *Cattleya labiata* in fine flower was enhanced by a front margin of this *Asparagus* and *Panicum* arranged alternately.

**Acer Lorbergi.**—A most distinct and handsome Maple under this name was sent to me many years ago by the late Louis van Houtte, of Ghent, and, being of a vigorous habit of growth, has now developed into a fine tall specimen. Its greatest merit, however, consists in the specially brilliant autumn colouring which its foliage assumes at this time of year, when every leaf becomes a clear canary-yellow, making the tree an extremely conspicuous and beautiful object in the shrubbery, and well worth planting by any lover of distinct and beautiful foliage trees. I do not find this name recognised in the "Index Kewensis," so that it may be known also under some other name at Kew. I enclose a leaf for your inspection.—W. E. GUMBLETON.

**Chrysanthemum Philadelphia.**—This variety, as seen almost everywhere this season, must, in my opinion, be regarded in the light of a disappointment. I remember some years ago a few blooms of Louis Boehmer being sent from America. In that case the petals were broad and stout, but under English cultivation they assume very narrow proportions. In the case of *Philadelphia* much the same complaint can be made. The blooms sent here last season were fine, solid, massive-looking, and quite different from those grown in this country during the present year. And as to the colour, instead of its being a pure white, faintly tinted primrose or sulphur, I have not seen a single bloom that could be compared with the American-grown examples. All those at the large trade displays and those shown at the Aquarium were distinctly yellow in colour.—CHRYSANTH.

**Orchids at Kew** now in flower are sufficiently numerous to give to the house devoted to them much welcome colour in the dull, cheerless days. About a dozen plants of *Cattleya labiata* down one of the side stages in the cool division are well flowered, and *C. Bowringiana* is represented by several good pieces, the finer spikes having each ten flowers upon them. The ever-welcome *Cypripedium insigne* makes a graceful bank at the end of the central stage. *C. Spicerianum* still has fresh flowers, and *C. Pitcherianum*, with its short broad sepals and petals and blunt, much-inflated pouch, is a very distinct form. *Lælia Eyer-*

*manniana* in tender mauve, shading to lilac and soft purple, is a delightful and uncommon species now carrying a good raceme of blooms; whilst the brilliant *Sophrontis grandiflora*, so vivid in colour, never fails to arrest attention when in flower.

**Dracæna Godseffiana** was noted in great numbers in the St. Albans nursery. It is free in growth, easy of increase, altogether unique among *Dracenas* alike in habit of growth and variegation, and certainly a plant that will be extensively grown in the future. It is more like an *Arundinaria* than a *Dracæna*, sending up cane-like shoots, the branch arrangement more or less in whorls, while the leaves much resemble those of a hardy Bamboo. In lovely colouring of the foliage, however, there is nothing like it among plants grown under glass. The leaves are quaintly blotched and spotted with yellow on a shining deep green ground, after the manner of those of the variegated *Aucuba*. It further adds to the value of this *Dracæna* that its long shoots can be cut for use in decoration, as they stand well and there is no loss of plant, many shoots arising from an underground culm.

**Byford Wonder Apple.**—This new Apple is apparently justifying all that was said in its favour a year or two ago in THE GARDEN. Numerous growers who purchased small trees worked on the English Paradise have recently shown me very fine fruit from trees only planted a year ago. At the Hereford fruit show some splendid dishes were staged from small trees, and so far the vigour and constitution of the variety leave nothing to be desired. No doubt next year it will come to the fore more than it has yet done, as the shoots are well furnished with bold fruit buds; not only so, but the trees being larger more fruit will be produced. Evidently some of our leading nurserymen have formed a very high opinion of its value, as they are working up large stocks to meet the anticipated demand. We have far too many varieties of Apples, but there is yet room for more of the Byford Wonder stamp, which combines great size, excellent cooking qualities, and the merit of keeping sound until March.—W. G. C.

**Carnations in Savoy.**—Miss Willmott, writing to us from Aix-les-Bains on October 23, says, "Carnations are as lovely as ever; masses of bloom and the whole air round scented by them. They consist of all kinds of Carnations, English, French, and German, from Hochard, Benary, Heinemann, and a great many from the Lyons growers. We take about 10,000 of our own cuttings in the autumn and keep in frames until the spring, and then plant out. We sow seed from wherever we can get it, including our own. We buy in from Lyons, Germany, &c., and plant out now. So you see we have all kinds and treat them in many different ways, and they all bloom equally well; different treatment seems to have no effect upon the way they bloom. We pick basketfuls of Carnations, flowers and buds, and the grass is so lovely. We have a large quantity of Marguerites, Venetian and French, and there are such lovely colours among them and such good flowers, as well as such delicious scent."

**A garden without a gardener.**—The council of the Royal Botanic Society having decided to dispense with the services of a garden superintendent, Mr. Coomber will therefore be open to a re-engagement.

Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## ORCHIDS.

### LÆLIA ANCEPS.

THERE is no more useful winter-flowering Orchid in existence than this beautiful and well-known species. It is plentiful enough to be always cheap, very constant and free-flowering, and one of the easiest of Orchids to manage. It is, moreover, a very variable kind, and if a good stock of plants is grown, the flowering season extends over a period of several of the dullest and most cheerless months in the year, the bright and pretty blossoms having a very telling effect when interspersed with Maiden-hair and other Ferns in winter groups in the conservatory. The flowers open at a time when the plant has quite finished its growth, and therefore the dry atmosphere necessary to conserve them is not so injurious to its health as in some other kinds that are flowering and growing at the same time. Very soon after the blossoms fade the new growths appear at the base of the pseudo-bulbs, and on this account the repotting or surface dressing that is usually needed once a year should be early attended to. *L. anceps* may be grown in a variety of ways to suit the fancy of individual growers. The plants have a very natural and striking appearance when in blossom if grown on large, rough pieces of Apple or Pear wood with the bark retained and a thin layer of Sphagnum Moss about them. An advantage accruing from this mode of culture is that the rhizomes as they extend do not carry the roots out of the reach of the compost as they do in pots or baskets, for the Sphagnum may be added to if necessary until the pieces of wood are covered, and this, of course, without disturbing the roots. Baskets may also be used, but the erect spikes of bloom do not look so well as those of a pendulous habit under the circumstances. Pots or wide, shallow pans are the most usual receptacles, and, all things considered, are probably the best, the plants being more readily attended to as regards watering and more easily moved about for cleaning and examination. They should be large rather than small in regard to the size of the plants, as this admits of their being left for at least three years in the same pots, the surface only being renewed annually. With these wide pots only a thin layer of compost will be needed, so the drainage may be placed right up to within an inch or so of the rims. The usual peat and Moss mixture, of good quality and in a rough and open condition, may be used, and plenty of charcoal or potsherds must be added as the work of potting is in progress. Very often the roots will have obtained a firm hold of both the inside and outside of the pots, and these must not be disturbed more than necessary, as they are usually the strongest and healthiest of all, being the last set produced. The pots must be broken and the pieces with roots attached placed in the new ones. If large pieces of the pots come away it will be necessary to place them down among the drainage, filling up around with crocks after the plants are placed in position, carefully avoiding breaking the roots in the meantime. A much less satisfactory state of affairs is when many of the roots, through growing in a close, heavy, or waterlogged compost, have perished, the remainder being

weak and unhealthy. Here the only thing to be done is to retain a few of the best of them to hold the plant in position and cut away all the rest, using a smaller pot than usual and mixing more Sphagnum and potsherds with the compost. In all cases where possible the leading pseudo-bulbs should be kept well back from the rims by pegging down, or, if the plants are healthy, notching the rhizome so that it may be bent in the direction desired. The pseudo-bulbs must be kept rather above the rims, the compost bedded around them firmly, and all ragged ends neatly trimmed off. They may be placed in the cool end of the Cattleya house, or in a temperature intermediate between this and that of the cool house. In either position they will do well provided they are not unduly shaded and have abundance of fresh air moving about them summer and winter.

While root and top growth are both active few Orchids require more water if potted as described above, but after the pseudo-bulbs are fully matured very little will suffice, only enough in fact to keep them plump. The leaves and bulbs are apt to become infested with white scale, and this if allowed to make headway soon spoils the appearance of the plants. Sponging with warm soapy water is the best remedy, and this should be resorted to very frequently until a complete riddance is made of the insects. *L. anceps* is an old species in cultivation, having first flowered in England more than sixty years ago. It is a native of Guatemala and Mexico. The typical flowers are each about 4 inches across and borne on erect spikes containing from two to five. The sepals and petals are deep rosy mauve, the lip bright purple, with white and yellow markings. The earliest flowers opened with me on the last day of October. Among the many fine varieties may be named

*L. ANCEPS AMESIANA*, a superb, nearly pure white variety, very lightly suffused with a delicate blush-pink, becoming more marked towards the tips of the sepals and petals. The latter are very broad and of great substance, the lip being pure white on the side lobes, the centre one purple.

*L. A. ALBA* when true is of the purest white, with no trace of any colour save a single yellow marking on the lip. But many varieties sold as alba are not pure white, and it is only by purchasing plants in flower that the true type can be ensured. This and several other white kinds are said not to flower so freely as the more highly-coloured forms, but this is often on account of their not being well established, plants that have a good hold of the compost usually blooming freely.

*L. A. BALLANTINIANA* is a choice and rare form with large flowers very full, and with broad, handsome segments. The colour throughout is a very pale rosy white, the lip having the usual crimson-purple streaks on the side lobes and a purple blotch in front.

*L. A. BARKERIANA* is a somewhat smaller variety than many, but distinctly coloured. The sepals, petals and lip are all of them narrower than in the best forms, the ground colour being deep magenta, that of the lip being the most intense, with a yellow crest.

*L. A. DAWSONI* is a superb form, and though by no means new, has not appeared in many collections. The flowers of this variety are characterised by their pure white sepals and petals of great size and substance: the lip is also white, with lines of purple inside; the centre lobe is rosy purple margined with white. This is named after the late Mr. T. Dawson, of Meadowbank, in whose once-celebrated collection it first flowered.

*L. A. DELICATA* is a small, but prettily-marked variety, well worthy of attention on account of its distinctness. The sepals and petals are very pale mauve, the lip white, with

the usually radiating lines of purple and a rich yellow disc.

*L. A. HILLIANA* is another of the white varieties, and a very fine one. It is not unlike the var. *Amesiana*, but the petals are, if anything, of a purer white. The plant is very vigorous in habit and produces much larger pseudo-bulbs than the type.

*L. A. SCOTTIANA* bears very large flowers with deep purplish segments, the lip being darker than in any other kind and having an orange-yellow throat. One of the most beautiful varieties of all is

*L. A. STELLA*, which has pure white sepals and petals, the lip yellowish, veined on the inside with deep purple and without the usual purple blotch.

There are many other varieties and new ones are being constantly added to the list, but enough have been mentioned to show the importance of this beautiful winter-flowering Orchid and its great value in keeping up a display. H. R.

### ORCHIDS FOR WINTER FLOWERING.

DURING the dull months of November and December, when the borders outside are bare and but few occupants of the stove and greenhouse are in bloom, it is pleasant to enter the Orchid house and there find lovely flowers greeting one on every side. First amongst them we have *Cattleya labiata* and its varieties, which bloom so freely at this time of the year that no garden ought to be without some of them. Being of such dwarf compact habit, they may be grown in small pots; therefore a goodly number will only occupy a limited space. *Lælia Perrini*, *L. anceps* and its varieties are all good for winter flowering, and should be included in every collection. Amongst the *Cypripediums* there are so many good things, that it would be a difficult task to say which was best. The old *C. insigne*, however, is still a great favourite with most people, its flowers being cheerful and lasting such a long time in water. This is one of the easiest Orchids to cultivate, as it is not particular either to temperature or soil so long as plenty of water is afforded during the growing season. Then there are the *Calanthes*, so charming for cutting, or as pot plants intermingled with *Asparagus* or *Adiantums*. The old *Zygopetalum Mackayi* should on no account be forgotten, and though its flowers are not so attractive as those of some other Orchids, their delicate perfume is very pleasing. *Oncidium ornithorrhynchum* and its white variety are well adapted for making sprays, and as they flower so freely ought to be grown in quantity. *Dendrobium Phalaenopsis Schrederianum*, *D. aureum* and *D. nobile* are all grand plants for flowering during the winter and all are of very easy cultivation. *Vanda Amesiana* and some of the *Pleiones* may also be grown; the latter, however, are of little value for cutting. There are of course many others, but the choicest are not always the freest flowering; it is better, therefore, for those who have a quantity of flowers to produce to grow the more common varieties to ensure success. From those named above it will be possible to cut flowers all through the dull months. Many *Odontoglossums* may also be had in bloom. *O. Rossi majus* is a grand one for this purpose, and though its spikes are not large the plants flower freely, and being of such compact growth take up but little room. Some of the *O. Alexandræ* that flowered early last season and have been encouraged to grow, will now be sending up their flower-spikes; the most forward should be placed together at the warmest end of the house. Slugs are so fond of these, that they will travel a considerable distance to get at them. Much watchful-

ness and care will on that account be needed to preserve the spikes from their ravages. Thrips are also very troublesome at this time of the year, especially where the houses are not properly ventilated and plenty of moisture kept about the stages and paths. So far there has been but little necessity for fire-heat in the cool structures, as the requisite temperature could be maintained without it. With care and a little forethought there is no reason why the Orchid houses should not present a gay appearance even during these dull months. H. C. P.

#### DENDROBIUM DRACONIS.

NONE of the nigro-hirsute section of the genus *Dendrobium* is constant in the time of flowering, and this fine species, though it usually blooms in early summer, occasionally throws a chance flower or two in autumn. The flowers are not unlike those of *D. Jamesianum*, but the segments are narrow and more pointed. Although it is better in all cases to keep the plants of these hairy kinds to a proper annual routine of growth, it is not always advisable to force them to rest by means of a lower temperature or a lessened water supply. If new growths start they must be kept going, for suppression of these only means either the formation of others at a later date, which will be weaker, or the plants go blind, as it is termed, and refuse to start at all. *D. Draconis* is a fairly strong grower, and as a rule more amenable to culture than most of this group. It delights in a very high and moist temperature while making its growth and a position hugging the glass in a light house. While the growths are young the leaves are very apt to be scorched by bright sunlight, but if gradually inured to this, they will by the time the pseudo-bulbs or stems are nearing completion be able to withstand a full supply, only lowering the blinds, in fact, for about an hour in the middle of the day, closing the house early with abundance of atmospheric moisture, and raising the shading at the same time. This produces the kind of heat that tropical Dendrobes delight in and is fatal to red spider, their most troublesome insect enemy. This species does not thrive well if overburdened with compost, even large specimens doing best with a layer of about an inch. They may be grown either in pots or baskets, while some growers use large trellised blocks with the best results, on account of the freedom with which the air circulates about the roots. Two-thirds of Sphagnum Moss to one of the best fibrous peat will make the best compost for the roots, but abundance of charcoal, crocks, or similar material must be intermixed when placing in pots or baskets. The latter will not of course be necessary on the rafts, as the teak rods answer the same purpose. Being an evergreen species, it must not be over-dried after the growths are complete, but a lessened supply of water will of course be needed. Nor must the winter temperature rule below 50° for plants at rest, while if growing, 10° higher should be afforded. The flowers are produced from near the top of the last matured stems or pseudo-bulbs, which are from 9 inches to 1 foot in height, small at the ends and somewhat swollen in the middle. *D. Draconis* is a native of Moulmein, whence it was introduced in 1862.

*Odontoglossum crispum roseum*.—Several forms of this variety are now in bloom, and it is very interesting to note how the flowers vary, not only on different plants, but on the same one, and even in some cases on the same spike a good deal of difference exists. A very pleasing form I noted recently had the sepals broad and overlapping, being also fringed or toothed on the edges. These were wholly of a faint rose without any spot, and the lip had several spots of yellow. Other forms have a broad stripe running up the centre of each segment of a deeper colour than the rest of the flower. Indeed, there seems to be almost as much variation in these rose-coloured

forms as in the ordinary white varieties, to which they form a most pleasing contrast.—R.

*Odontoglossum tripudians xanthoglossum*.—This is a distinct and pretty form of this old species, much deeper in colour than the type as usually seen, the lip being nearly covered with large purplish blotches. Some of the better forms of *O. tripudians* are certainly deserving of more attention than they at present receive, for not only are the blossoms large and rich in colour, but it is one of the freest blooming kinds in existence, rivalling even *O. triumphans* in this respect. It thrives well in the coolest house, and was introduced from Peru in 1869.

*Oncidium barbatum*.—This pretty little species is now in flower and worth a place in representative collections. The plant is of a tufted habit, with small, roundish pseudo-bulbs and leaves only about a couple of inches in length. The small flowers, produced on slender erect spikes, are bright yellow with brownish red spots on the sepals and petals. This plant does best suspended from the roof in a shady part of the Cattleya house, and should be grown in shallow pans of peat and Moss. A little of the surface of the compost should be removed annually and new substituted, this being preferable to frequent repotting.

*Oncidium carthaginense*.—Several newly-imported pieces of this Orchid are throwing up vigorous spikes, and a good deal of variation exists among the flowers. A pretty variety has flowers of a very pale purple, almost white, with many crimson spots and markings. It is a strong, healthy growing plant, and one of the easiest of all Orchids to grow or establish. Plants purchased last May have now filled their pots with roots and produced new leaves nearly as large as those preceding them, thus showing that the check given by their journey was only slight. It is a native of Honduras, and thrives well in the Cattleya house.

## STOVE AND GREENHOUSE.

### SICKLY PLANTS.

OVER-POTTING is responsible for the loss of innumerable plants, and many more that are over-potted linger on, proving an eyesore to all concerned. Sometimes it is not so much a case of over-potting as of the use of unsuitable soil, or it may be the mixture is right enough, only the water used tends to cover it with black slime and to sour it. Some plants are repotted oftener than either desirable or needful; others are kept restricted at the roots and fail to take kindly to the fresh soil when given a shift, while many are repotted at the right time, only to be spoilt by careless watering afterwards. The question is sometimes asked, What becomes of the thousands of Indian Azaleas that are every year imported into this country from Belgium and elsewhere? Judging from my experience in different localities, they are widely distributed; most of them flower grandly the first season and never properly afterwards. Those who buy them from our nurserymen either overlook the fact or else are unaware that the majority of these plants are dug out of pits and frames and are potted by those to whom they are sent. It follows that the new soil is not occupied by the roots, and is not likely to be till after the flowering is over. There should, then, be no repotting or shifting of the plants by their new owners for at least one year, and, as a rule, they would do well in the same comparatively small pots a second year, always provided they were well attended to. In any case only small shifts should be given, and no transferring from 5-inch pots to any nearly

three sizes larger. Nor ought they to be turned out of doors directly the summer appears to have arrived. After flowering they should if possible get more warmth than previously in order to develop fresh strong growths for flowering next season, and unless thoroughly well rooted ought not to be set outside at all. At the present time there are thousands of Indian Azaleas in a sickly plight owing to being over-potted and the soil overrun by worms. It is not the best time of year to repot Azaleas, but rather than leave the plants in such a plight I would prefer to clear them of the soured soil, retaining the original ball of soil and roots in its entirety, and placing in much smaller pots with a peaty, firmly packed compost. Azaleas ought never to become very dry at the roots, but those over-potted must be very sparingly watered, or the whole of the roots may quickly perish and the plants die. Camellias have gone out of fashion, but those who have them will do well to avoid over-potting and should give them some lime-water if worms are in the pots. Other hard-wooded greenhouse plants are becoming scarcer than ever, the rage being for plants that can be raised quickly and cheaply, and which are capable of affording abundance of flowers.

What a number of sickly Persian Cyclamens are to be seen everywhere. Every gardener seems to recognise the value of this class of plants, and grows a few or many accordingly, but only in a small number of cases successfully. Old corms are kept long after they can be made to produce good-sized flowers freely, while the young or one-year-old plants usually look lost in their pots. Young plants from the time the seed has germinated, and this should take place very early in the year, ought not to have a check given to them in any way—such for instance, as a few weeks in small pots on a dry, sunny shelf very often bring about, as no amount of skilful treatment will recover them from this. Throw those feeble plants away instead of trying for the next two years to grow them to the size they ought to have been within nine months of the time of sowing the seed. Chinese Primulas in larger pots than they can very well fill must be very carefully watered indeed, or otherwise they will rot off. Semi-doubles from seed are quite as easy to grow in an ordinary greenhouse temperature as are the single forms, but the old semi-doubles, propagated by means of cuttings or division, are not. It is an intermediate temperature that best suits these, and a shelf not far from the glass rather than a low staging with perhaps a variety of taller plants behind them. In low temperatures and large pots they are of little service, and gradually dwindle away. Kept in low temperatures and a badly root-bound state, *Clivias* present a starved appearance and flower unsatisfactorily; whereas they are much healthier when rooting in fresh soil, or say after large, old plants have been freely divided and each strong division given an 8-inch pot. I have tried what liquid manure would do for these starved plants, but it does not improve them much. It is in an intermediate temperature where the fewest mistakes are made with this beautiful class of plants.

At the commencement of October Crotons may be in excellent health, the foliage being fresh and well coloured, but by mid-winter the same plants are not unfrequently in a miserable plight. Fire-heat unaccompanied by a free use of the syringe or much moisture in the atmosphere favours the spread of red spider and thrips, and these quickly spoil the appearance of Crotons and also *Dracenas*. Timely gentle fumigations will keep down thrips. Very many *Ixoras* are

over-potted, and it is at this time of year when they show the ill effects of this the most. Healthy young plants strongly rooted, kept free of mealy bug and thrips and given plenty of heat, produce fine trusses of flowers up to mid-winter or later. Throw away the stunted sickly old plants and raise vigorous young stuff in their place. Keep *Dipladenias*, more especially those of the *amabilis* type, in a brisk heat and quite on the dry side at the roots. It is the over-potted, imperfectly ripened, and not well-rested plants that start into growth the least satisfactorily and are the most likely to remain in a sickly state. *Dipladenia boliviensis* is the most easily grown and flowers freely during the greater part of the year. Old plants in pots are apt to become stunted and unhealthy in appearance, also giving the smallest flowers, and young ones should be raised from cuttings to take the place of any two years and upwards old. That beautiful stove trailing plant *Gloriosa superba* is not often seen at its best. Too many err in placing the bulbs or tubers in large pots, and when they are seen during the growing season to be of a sickly hue, the chances are that not a healthy root fibre is to be found. Give the bulbs a good rest in a stove heat, start in smaller pots next spring, and avoid over-watering, especially at the outset. If *Allamandas* are starved at the roots they are anything but "things of beauty." They are coarse, hungry-rooted plants, and whether in pots, tubs, or small brick pits should be turned out just as they are breaking afresh after being hard pruned in February, have their roots reduced considerably, and be given the benefit of a good supply of fresh and fairly rich compost. *Gardenias*, though strongly scented, are yet much appreciated as button-hole flowers and such like, and pay for high culture. In a sickly, mealy bug-infested state they are not worth house room. Young plants do well in pots and older ones planted out. A narrow pit with bottom-heat pipes, peaty soil, strong heat, and moist atmosphere suits this class of plants well. If the soil sours, and it is very apt to do so when the watering-pot and syringe are so freely used, as they ought to be, turn out the plants, syringe all the soil from the roots, and replant in fresh compost. This may be done at almost any time of the year, the plants not suffering in the least. Keep mealy bug under by means of the syringe, using either clear water or weak soot water rather than sponging with strong insecticides. *Eucharises* are more often seen in a sickly state than in a healthy condition. If overpotted and the soil sour they will not thrive, and in order to restore them to a more satisfactory state shake clear of old soil and syringe the roots prior to repotting in fresh soil, and they will recover all the more quickly if the old leaves are cut off, this also getting rid of mealy bug if any exists on the plants. Either early in the autumn or in the spring is the best time for treating *Eucharises* in this way. They should have the benefit of brisk bottom-heat for a time, and must not be heavily watered at the outset. Very many plants, *Eucharises* included, get into a sickly state owing to the soil in the pots having been soured by the action of worms. Where hotbeds of ether stable manure, leaves, spent tanner's bark, or any of them in mixture are formed, these materials decay quickly in much heat and moisture and soon become full of worms, some of the latter, as a matter of course, finding their way into all the pots arranged on or plunged in these beds. Years ago I gave up using such materials, preferring to arrange the plants on beds of clinkers and ashes, thereby keeping plants set on them free of worms. During hot

weather unplunged plants may need more water than do those plunged in heating material, and they must have their surroundings kept uniformly moist, but during at least eight months in the year the former have the advantage. At Hill House, Langport, *Eucharises* and other plants are in an admirable condition, and all are arranged on beds of clinkers.

W. IGGULDEN.

**Sericographis Ghiesbreghtiana.**—Some years ago this used to be grown extensively, and was looked upon as one of the most useful plants for winter flowering. When grown singly the plants require two years to make good, bushy, flowering plants. I used to bloom it well in 8-inch pots. When growing old plants on, they were cut back as soon as they had done flowering, kept in an intermediate house and repotted early in the year, using a rather light sandy compost and good drainage. The plants like a rather moist atmosphere while making their growth, and the syringe must be used freely to keep down red-spider. By the middle of July good-sized plants will have been made, and they should then have a period of rest, otherwise the bloom will not set. I used to put them out of doors in a sunny position and keep them rather dry for a time. They must be taken indoors again by the end of August, or earlier if the weather is bad, and they will then soon begin to show flower. I do not now remember exactly when the first blooms opened, but I think early in October, and they lasted till Christmas. When growing them on from cuttings, five or six plants may be placed in the same pot. It is essential to get the plants potted early, as late-potted plants, or those grown in the shade, will not flower freely.—A. H.

## FLOWER GARDEN.

### NEW HYBRIDS OF GLADIOLUS GANDAVENTSIS.

It is now about five and thirty years since I commenced the culture of this beautiful autumnal flower. I have witnessed its evolution from small beginnings, when spikes consisting of three or four flowers not one-third so large as some of the present day were considered objects of admiration. I have seen the rapid strides that they have made in every quality which can attract the attention of the florist. I have seen them with spikes of eighteen to twenty expanded flowers open at the same time, and instead of the flowers being back to one another in two rows as they used to be, they are now fully in view, and so close together that it would be impossible to insert a paper knife between them. I have seen these flowers so increased in size (though I put this as their last recommendation), that one bloom is fully equal to three of those we used to have, while nearly all shades of colour with the exception of blue are represented amongst them, yet with all this they are neither popular in the true sense of the word, that is, not widely grown, nor round the metropolis are there many occasions on which the public have an opportunity of seeing them. When I come to consider what the cause of this is I think it may be fairly traceable to two sources; in the first place, the *Gladiolus* is a very troublesome flower to cultivate successfully, and secondly, very disappointing, owing to the many losses which everyone who grows it has to deplore. I am frequently told by beginners who have been growing them perhaps for a couple of years that they have not experienced any losses, but after a few years their ardour cools and they drop out of the course. I have said that it is a troublesome plant to grow and it is a more

troublesome one to exhibit. There are a few months in the year, say from December to March, when they are quietly resting on the shelves, when they give no trouble, but from that on they are a continuous care. They must first of all have the ground carefully prepared for them (best done in the autumn), and then each bulb must be carefully examined to have the outer skin slipped off before planting, for it very often happens that to all appearance the bulb is sound, but when the skin is taken off it is found to be either withered or rotten. Then as the plants grow they have to be staked and tied, and every few days they have to be examined for this purpose; each bulb must have a stake to itself. Great care is also required that the spikes may be quite straight. In some cases this staking has to be done twice over, for, as the flowers are not fully developed, it may so happen that the stake may be in the front of the flower instead of in its proper place at the back. Those who are very careful about exhibiting will have cases to put the flowers into which they intend to show. After the *Gladioli* have done flowering they have to be harvested, each variety has to be kept distinct, the bulbs have to be cleaned and dried, the spawn has to be collected and to be put by in small paper bags, the bulbs themselves to have their names written on them, so as to avoid all mistakes, and placed in a cool place free from frost on shelves or trays, to remain there during the winter months. And what shall I say as to exhibiting them? Various plans have been tried. It is impossible to carry them lying down, as they rub one against the other, and consequently, whatever may be the form or character of the case in which they are carried, it must necessarily be a large one, and at the tender mercy of railway porters and others. Then, when you get them to the place of exhibition, they are not like a tray of Dahlias or Chrysanthemums—which you have only to draw out of the case and put upon the exhibition table—but each spike has to be taken out separately and tied to a rod in order to keep it in an upright position. Now I contend that there is no flower which we grow in collections that is so troublesome as this. Tulips are troublesome, but nothing like the *Gladioli*; and this is one of the reasons that makes me believe that the attempt to resuscitate tastes for that flower, showy and beautiful as it is, will not succeed in the south of England.

But there is also, as I have said, another drawback to general cultivation, and that is its tendency "to make itself scarce." You receive a bulb, or harvest it yourself, to all appearance perfectly sound; you plant it, it grows, sends up a great green shoot, the flower-spike forms, it begins to show colour, and then all at once it turns yellow and dies off, or it may even go so far as to flower well and immediately afterwards die off. Is it wonderful that with these conditions its admirers are many, but its cultivators few?

I now come to write of the novelties which I have had the opportunity of seeing during the past year, those I mean which I have grown myself and which I have had, therefore, time to examine. The following are novelties I have grown:—

**VALKYRIE.**—A long spike of scarlet flowers, flaked with slaty violet, a kind of colour which is not, I think, very much appreciated with us, although the French seem to regard it with favour.

**OLYMPIE.**—A very large flower and well opened, a deep rose colour shaded with lilac, with a pure white spot; a novel flower.

**TRIGILLIA.**—A flower of quite a distinct character, a curious shade of salmon colour, occasionally flaked with carmine-rose.

**DIADÈME.**—The finest yellow flower yet brought out; fine large spike with well opened flowers, apparently of a good constitution.

**GARGANTUA.**—A flower of exceptional merit, very large and very open, carmine-rose, profusely striped with violet-red and very light in the centre.

**BERRYER.**—Very bright coloured flower, cherry-red, lightly striped with lilac, with a large white spot: a fine spike.

**BEHANZIN.**—A fine distinct spike, another of those slaty flowers, but with a white line in each division, which lightens it up considerably.

**GERTRUDE.**—Very large flower with long spike of a white colour, suffused with pink; very striking.

**BERNICE.**—A good yellow flower, bearing a good deal of likeness to Souchet's Berenice, and, like it, apparently of a better constitution than the yellows we already possess.

**HILDA.**—A very beautiful and distinct ivory white flower, flaked on the edge with rose, pale yellow throat, good constitution, and a flower of good substance.

**ROSALIND.**—A pale rose flower with a long spike, flaked and striped with crimson, very distinct and large.

**DECIMA.**—A very fine spike of large, well-opened flowers, with a pale rosy white ground, flaked on the edges with crimson, novel and distinct.

When in these descriptions I make use of the terms large, well opened, good spike, they perhaps convey a very inadequate notion of the meaning of these terms. Take, for instance, that of size; I may say that a variety has large flowers, but so I might have said a dozen years ago of a flower which would be now considered far too small, but this must be the case in all things which are continually improving. I have said nothing in these notes of some of the new varieties of the Lemoinei type, although in fact just in proportion as they improve the nearer they approach to the gaudavensis type, than which I do not think they are more hardy, for if the same protection which Lemoine insists upon is necessary for them at Nancy, a very cold district of France, were to be given to the bulbs of the gaudavensis section, I believe they would be equally well able to stand our winters. If any amateur has a good, well-drained soil which will grow Strawberries well, I think that he would be likely to succeed with this beautiful autumn bulb, but he must be prepared for some disappointments, now much less to be lamented over than formerly, for he can by the expenditure of a few shillings replace his losses. There is certainly no more beautiful occupant of our gardens during the month of August and the early part of September than the stately and beautiful varieties of this charming flower. DELTA.

#### THE ENGLISH TULIP.

The Tulip is perhaps most charming in its variety, especially in its changes from the breeder or self-coloured state to its rectified or broken state. The bloom that last year was purple, that is, each petal purple with the exception of a small section of white at the bottom, which forms the base or ground colour, this year may break. The flower may be white, except a fine edging of purple round every petal, a feathered flower, or it may come beautifully marked in another way. In addition to each petal being edged all round with purple, it may also be marked with a sort of miniature Beech tree of purple, the trunk of the tree being the centre of the petal or beam, the purple colour branching outwards until it joins the edging or feathering, when it is called a flamed flower. The precise year this change or break may take place no one can foretell, but come at some time it assuredly will. Some bulbs continue to give the lovely self-coloured blooms for many years, while others soon rectify or break. It is somewhat surprising that this old English flower is not more often seen in our gar-

dens, as it requires no special skill to cultivate, and will grow well in town or country. From the time the bulbs are planted in November or December till about the following March no care or attention is needed. As to soil, that of the kitchen garden will do well, and no manure is needed if the ground has been enriched for the previous crop. Many beds are to be seen of the Dutch Tulips, but few of the florists' Tulip, yet one may obtain a hundred of the latter almost as cheaply as of the former. In earlier years no doubt the English Tulip was difficult to obtain and expensive, but it is not so now. One hundred mixed Tulips may be purchased for less than £1, and I am sure all who grow them will find great pleasure therein, and be surprised they have not grown the flower before. The English Tulip is later than the gorgeous Dutch variety we see so commonly in April and not so dwarf, its blooming time being the "merriemonth of May," and its flower-stem from 2 feet to 3 feet high. The uninitiated in Tulip culture may readily see that neither in form nor in colour does the Dutch Tulip approach the English florist's Tulip. The specimens exhibited at the Temple show last May showed very clearly that the Tulip may be grown to perfection in and around London.—C. W. N., *Royal National Tulip Society, Manchester.*

—The Rev. F. D. Horner, the late Samuel Barlow, Mr. J. W. Bentley, and other eminent cultivators of the amateur's English Tulip have with myself during many years past placed before the public, in writing and otherwise, the great pleasure and satisfaction which are derived by all cultivators of the Tulip. As most lovers of florists' flowers are already aware, the cultivation of the English show Tulip has during the last half century been almost exclusively confined to Lancashire, Yorkshire and the midland counties, in conjunction with the Royal National Tulip Society, and the great desire of the principal members of this society has been to occasionally encroach upon the space of the several London periodicals with a brief article upon the subject in the hope of encouraging the amateurs in the neighbourhood of London and in the south to cultivate this somewhat neglected florist's flower. It has been shown over and over again how largely and enthusiastically it was cultivated in the south during the early part of this century and for centuries previously. Many of the old southern growers' names might be enumerated, such as Strong, Lawrence, Goldham, Headley, &c. Thomas Hogg, in his treatise on the "Cultivation of Florists' Flowers," says, in alluding to those who were then cultivating Tulips: "To such I can with truth say that I have always been a great admirer of the Tulip. I esteem it the masterpiece of perfection, and it is the pride and boast of every amateur who grows it." It is easy for every Tulip grower to confirm Hogg in his sincere expressions, and it is at the same time gratifying to know that the trouble which has been taken during the last few years in keeping the show Tulip prominently before the public has met with its reward. Messrs. P. Barr and Son intend offering silver medals as prizes in conjunction with the Royal Horticultural Society at the ensuing Tulip exhibition, which will be held in London in May next, and strong efforts are being made to organise a Tulip congress to be held on the day of the exhibition.—JAMES THURSTAN, *The Green, Cannock.*

#### PLEASURE GROUND NOTES.

**BERRIED TREES AND SHRUBS.**—If there is any truth in the old saying that a hard winter invariably follows a profusion of berries, we are likely to have some sharp weather in 1895, for nearly all berry-bearing trees and shrubs are laden with fruit. This in the case of the Holly is somewhat remarkable, as two fruitful seasons consecutively are not often known. The common Holly does well with me and assumes the dimensions of a small forest tree, plenty of specimens being over 50 feet high and well furnished. When trees of this description are well berried, they are, until the

birds make a clearance of them, quite a prominent feature of the pleasure ground. The variegated and yellow-berried forms are also covered respectively with their light red and golden fruit. The profusion of berries is not confined to the Holly, all trees and shrubs being well supplied, from the Mountain Ash and Cratægus in variety to the Berberis, the common Brier of the hedgerow, and the Snowberries. Clumps of the last show quite a mass of the white fruit, and are just now a very pretty feature of the shrubbery. I notice also that several of the less known fruits employed occasionally in the pleasure grounds, as the Siberian Crab and the Apple and Pear-shaped Service, have been very heavily cropped.

**TRAILING PLANTS.**—Sundry places in many pleasure-grounds in the way of bits of steep banks, old stumps, bits of ruined walls, &c., that were formerly overrun with weeds, or at best covered with Ivy, are now often planted with flowering subjects that help to brighten up sites which would otherwise be quite given over to the prevailing greenery. Among suitable plants (to take only common things) are Clematis montana and C. flammula, the double pink and white Brambles, Lonicera brachypoda and L. aurea reticulata, Ceanothus azureus, a much stronger grower than the newer kinds, and therefore more suitable for rough places, with such Roses as Aimée Vibert, Blairi and Turner's Crimson Rambler. The first and last-named would have a beautiful effect so planted that their branches and flowers would intermingle. Several correspondents have referred lately to the very fine show made this season by Tropæolum tuberosum and T. speciosum, and, given suitable situations, they make very beautiful trailers.

**CLIMBERS.**—In one or two instances climbing plants on walls were badly cut last winter, and if any gaps exist now is the time to fill them up. Flowering plants should as a rule be selected, the proportion of these to anything evergreen with insignificant flowers or a very short-lived season being at least in the ratio of two to one. A good half-dozen would be Ceanothus Gloire de Versailles, Chimonanthus fragrans, Escallonia Philipiana and E. sanguinea, the white and rose-coloured Pyrus and Spiræa prunifolia fl. pl., with perhaps Berberidopsis corallina and Aloysia citriflora. The two last-named will require a little protection in sharp winters. In the case of old-established climbers that happen to be overhanging walls, they may receive a little attention as soon as the leaves have fallen in the way of the removal of any superfluous shoots, and tying in others that will be needed later on to replace any that may require removal. Anyone new to the work will require a caution not to remove anything in the way of flowering wood, or at least only what may be absolutely necessary.

**HARDY PLANTS FOR THE PLEASURE GROUND.**—The mention above of the Lemon-scented Verbena reminds one that where the supply of foliage for cutting is not very abundant, a few plants for this purpose may be put in on outlying borders, or, if none such exist, a portion of rough shrubbery may be cleared to make room for them. There are also many of the strong-growing herbaceous plants that may with advantage find a permanent home in such situations if there is little accommodation for them in the regular garden. They invariably do well on the site of an old shrubbery if, after the removal of the shrubs necessitating a deep working of the ground, a liberal dose of good holding manure is trenched in. The advantage gained by such planting is not only the brightening up of hitherto dull places, but a liberal supply of flowers, thereby saving the display on more prominent borders. Such sites, too, being, as a rule, sheltered and a little shaded, the flowers last longer than when fully exposed to a hot sun. As such borders generally get the benefit of the leaf fall, it is as well to leave the latter all over the surface, and later a very thin sprinkling of soil may be shaken over them to prevent a high wind blowing them about. E. BURRELL.

*Claremont.*

SNOWDROPS.

Pretty firstling of the year,  
Herald of a host of flowers.

Of all our flowers there is perhaps none that appeals more closely to the heart than the Snowdrop—no sight that we would less readily relinquish than that of

The wan Snowdrop sighing for the sun  
On sunless days of winter,

for, although we feel that there is truth in the old adage "As the days lengthen the cold will strengthen," the silent sermon preached by the modest down-bent head is

Out of the snow the Snowdrop,  
Out of death comes life—

that, out of the death of winter is coming—though afar and all too reluctantly—the life of returning spring, and the glad certainty possesses us that

The sap will surely quicken soon or late,  
The tardiest bird will twitter to a mate,  
And spring will dawn again with warmth and bloom.

It is true that when the scent of the Prim roses and of the white Violets fills the air, and the wild Hyacinths spread their azure, sky-bright carpet beneath the grey-stemmed Beeches, the pale harbinger of spring will for a space sink into oblivion. Such involuntary inconstancy is but the outcome of that creed which teaches us the worship, not of one flower alone, but of all, as the charms of each are in turn unveiled by their guardian goddess Flora. Each fresh blossom unfolding its beauty seems that very acme of loveliness for which we have been waiting, until outshone by yet another rival; and, as with the form and colouring of flowers, so is it with their scents. Lives there anyone who can affix a standard of preciousness to their perfumes? Who can critically discriminate between the values of the fragrance of Clove, Carnation, Lily of the Valley and the Cabbage Rose? But, after all is said, however much the praise of other flowers may be sung, the "Fair Maid of February," the

Flower that first in the sweet garden smiled,  
To virgins sacred and the Snowdrop styled,

may rest content in the knowledge that at her shrine are the first fruits of our homage offered.

Snowdrops are intimately connected with the recollections of childhood. We remember the little plots where we planted them, the daily, nay, almost hourly visits paid to see if they were "up"—the white patch we espied beneath a Blackthorn hedge, which, to our delight, proved to be a clump in full bloom.

In poetry the Snowdrop stands unrivalled, save by the Lily and the Rose. It was the Snowdrop that Tennyson's pathetic creation, the May Queen, longed of all flowers to see again before she died—the Snowdrop, that on St. Agnes' Eve, within the snow-clad convent, lay in the bosom of the novice—the Snowdrop that Scroope and Barry Cornwall wrote of—the emblem of chastity, of graceful maidenhood, pure with the purity of the virgin snow.

Beautiful always, it is only when naturalised that the Snowdrop can be appreciated at its true worth. Then may one see grassy aisles between the Rhododendrons aglitter with hosts of pendent bells and leaves blue-grey—colour of the eyes of Athene—and on a moonlight night mark the white chalices glisten with a satin sheen in the cold, clear air. It is, however, beneath the overarching tree-boughs that the fairest vision of these vestals of the wood is gained. Along the open woodland paths, in a broad wavering line, their countless blossoms gleam, a veritable galaxy, rivalling the Arab's

"silver riband," the "milky way" of the firmament. Around the boles of the giant Oaks, up whose gnarled trunks the grey nuthatches climb, peering assiduously into every crevice, and by the margin of the moorhen-haunted lakelet, they stand in their thousands, venturing with

the more recently-introduced hybrid Aquilegias are extremely chaste and beautiful, but they have not the vigorous constitution that chrysantha possesses, and require a favourable situation to do them well. Moreover, *A. chrysantha* produces its flowers (which are of a clear canary yellow) on

long stems from 1 foot to 18 inches in length, this fact alone enhancing their value for cutting. The new hybrids grow very well with me in a sunny position, but on a north border, where I tried them with a view to secure a longer succession of bloom, they failed. Even on a west well-drained border I find it best to mulch the surface of the ground in November with rough leaf-mould, as if there is much rain during the winter, followed by severe frost, many of the plants die off. I consider the best forms of Aquilegias in their many rich hues equal to the choicest Orchids.  
—J. C.

*Snowdrops naturalised. Engraved for THE GARDEN from a photograph by Mr. S. W. Fitzherbert, Lanscombe House, Torquay.*

the Ivy tendrils to the very brink, where with downcast eyes they gaze at the argent shimmering of their pure images in the dark, still water.

S. W. F.

**Aquilegia chrysantha.**—In my opinion this is about the most valuable of all the Aquilegias for cutting and for massing in borders. Many of

bulbs, green stems, broader and much paler leaves, while the tube of the flower is shorter, the interior less white, and the chocolate outside not so deep as in *L. Browni*. A coloured plate of a very distinct form of *L. Browni* was given in *THE GARDEN*, February 9 of the present year. This variety (*leucanthum*) flowered at Kew from bulbs sent by Dr. Augustine Henry

LILIES IN 1895.

THE year 1895 has not been marked by the advent of any particularly new Lily, and the only one to which a first-class certificate was awarded by the Royal Horticultural Society is one of the oldest members of the genus, viz., *Lilium odorum*, known also as *L. japonicum* and *L. japonicum Colchesteri*. It was shown under this last name when the certificate was awarded—why, it is impossible to say, for the specific title of *odorum* certainly claims priority, but even then authorities do not agree, as Mr. Baker considers *L. odorum* to be the correct name, while in the "Dictionary of Gardening" it is called *L. japonicum*, with *odorum* as a synonym. In any case it is a very beautiful Lily, belonging to the puzzling Browni group, but a good deal more delicate in constitution than the typical Browni—that is to say, the form grown so successfully by some of the Dutch cultivators and sent to this country. Notwithstanding assertions to the contrary, this Lily is never sent from Japan during the winter months, but from that source *L. odorum* reaches England in considerable numbers. It is, however, likely to always remain comparatively scarce, as many of the bulbs die the first season after planting. In a few words, the most marked points of difference between *L. odorum* and *L. Browni* are, in the latter the bulbs are reddish, the stems dark, the leaves deep green, and the flowers ivory-white inside, heavily tinged with chocolate on the exterior. *L. odorum*, on the other hand, has yellowish

from the interior of China, the magnificent *L. Henryi* being also sent at the same time. The drawing for the plate was of course prepared in 1894, but the Lily in question also flowered grandly this year. Another variety, *Chloraster*, is also grown at Kew. *Lilium Dalhansonii* is the only other Lily that was recognised by the Royal Horticultural Society during the year, and this received an award of merit on June 25. It is of hybrid origin, having been raised by Mr. Powell, of Southborough, Tunbridge Wells. It belongs to the Martagon group, the parents being the dark-coloured variety of *L. Martagon* known as *dalmaticum* and the Japanese *L. Hansonii*, whose yellow blossoms are dotted more or less with reddish brown. The hybrid is of good vigorous constitution, and in general appearance about midway between its parents. Being of easy increase, it will no doubt soon become plentiful. This Lily is by no means new, having first flowered with Mr. Powell in 1890, and a very characteristic coloured plate of it was given in *THE GARDEN*, September 16, 1893. A pretty and interesting Lily of hybrid origin that flowered, as far as I know, for the first time with Mr. Ware at Tottenham is *L. Beerensi*, said to be the result of a cross between *L. chalcedonicum* and *L. excelsum* or *testaceum* (itself a hybrid). The flower is of a pleasing shape and deep apricot in colour.

Occasionally some singular Lilies may be picked up at the London auction rooms, and last spring among a number of Japanese bulbs was a quantity offered under the name of *L. elegans davuricum*. The bulbs were very much like some form of *elegans*, notably one that is frequently imported from Japan and known as *L. elegans marmoratum aureum*, *robustum*, or *guttatum*. They, however, turned out to be quite distinct, and, judging from the individual differences to be found among them, were, I should say, seedlings. The bulk consisted of one type, the plants reaching a height of 2 feet to 3 feet, the stem being thickly clothed with narrow leaves, 3 inches or a little more long and dark green in colour. The major portion of the petals is of a salmon-red tint, which changes in the centre to more of an orange hue, dotted with chocolate. The petals are narrow, and expanding as they do more widely than in any of the varieties of *L. davuricum*, they form quite a starry flower. During the growing season a very prominent feature of this Lily is the excessive wooliness of the young leaves and flower-buds, and even before the buds make their appearance the growing central portion of the stem is simply a white woolly mass. The remarks will apply fairly well to the majority of these Lilies, but a few were of a deep orange, flaked irregularly with crimson, and in two or three cases the colours were reversed, the crimson preponderating. In these flaked forms the flowers did not open quite so widely as in the others, being, in fact, as far as shape is concerned, more like those of *davuricum*, but in all cases the foliage was the same. In some of the latest flowering the colour was the same as that of the bulk of these Lilies, that is, a salmon-red with an orange centre, dotted with chocolate, but instead of being arranged in an open head these were disposed of more in a deltoid raceme, as in *L. croceum*. A very noticeable feature in connection with these Lilies was the lateness of their blooming period, which to a certain extent was doubtless caused by the fact that these bulbs were not sold till March 13, but in any case they were exceptionally late, for I noted good fresh flowers and unopened buds as late as July 20, at which period nearly all the cup-shaped Lilies were over. Some good examples of this Lily were very attractive in Hyde Park during the summer. It is probably of hybrid origin, perhaps between *L. davuricum* and some variety of *L. elegans*, which may be *marmoratum aureum*, as in this the young foliage is very woolly, but hardly to such an extent as in the new-comer.

Though there is little to say concerning new Lilies, yet some of the recent introductions have this season been more generally grown. *L. nepalense* is an instance of this, for considerable im-

portations reached this country early in the year, so that it was possible to buy bulbs at a much cheaper rate than formerly. The Nepal Lily is very effective for grouping, as, owing to the tall slender style of growth, an isolated specimen or two is not seen at their best, but the gracefully-reflexed distinctly-marked blossoms are very telling in association with other plants. The bulbs frequently remain dormant till spring is well advanced and the flowering is somewhat irregular, there being, if a quantity is grown, sometimes an interval of three months between the first and last blossoms. For late flowering, some examples will hold their own with the Neilgherry Lily (*Lilium neilgherrense*), for I noted good plants of *L. nepalense* in bloom as late as November 14. It does not seem to retain its vigour long in this country, and, like some other Indian Lilies, it is very probable that in order to ensure a good display of blossoms every year annual importation will be necessary. *L. Lowi*, which, like *L. nepalense*, is essentially a greenhouse species, is certainly very distinct, though less showy than some of the others. It still remains one of the rarest of all, though it is more grown than was formerly the case. The white bell-shaped flowers, dotted with purple, are, as a rule, borne during the summer months. *Lilium Lowi* naturally grows with *L. nepalense*, and another charming Lily, *L. sulphureum*, which about half a dozen years ago, when first flowered by Messrs. Low, attracted a large share of attention under the name of *L. Wallichianum superbum*. It is a tall, stately-growing Lily, whose funnel-shaped, whitish blossoms are tinged with red outside and in the interior with rich yellow. This Lily seems more robust in constitution than the other Burmese species, and for the embellishment of a large structure towards the end of the summer, and often well on into the autumn, it is very valuable. *L. Henryi* improves year by year, and it must, I think, be regarded as one of the very best Lilies of recent introduction. The English climate seems to suit it exactly, for even small bulbs soon attain flowering size, and the winter seems to have no effect upon it. Considerable numbers of this Lily were imported early in the year, and as in nearly every case they continue to improve, it is now often seen. A noticeable feature of the four Lilies just mentioned—viz., *L. Henryi*, *L. Lowi*, *L. sulphureum* and *L. nepalense*—is the great resemblance the bulbs bear to each other, so that it is impossible to select them with certainty. *L. Alexandræ*, which first came into notice two years ago, when it received a first-class certificate from the Royal Horticultural Society, has been little seen this year. It is a very distinct Lily, which when it first flowered was said to be a hybrid between *L. longiflorum* and *L. auratum*. Its general appearance certainly suggested that such might have been its origin, but that it was artificially produced would appear to have been disproved. In the spring of 1893 some very fine bulbs of this Lily were sold under the name of *Lilium Uke-uri*, and they flowered beautifully, but I have not seen such fine bulbs since. With care it seems to improve under cultivation. In the early part of the year a considerable quantity of *L. Alexandræ* could be obtained, but the bulbs were too small to flower this season; hence they were not much sought after. *L. Grayi* is another of the newer Lilies, but instead of being a native of the eastern hemisphere (as are all the preceding), it comes from North America, and is a very near ally of *L. canadense*. The flowers of the new-comer are somewhat smaller than those of the Canadian Lily and less expanded. Their colour is deep crimson-red, the inside freshly dotted. The bulbs of this are of a peculiar rhizomatous growth common to the Panther Lily and two or three others.

Of the old thoroughly established species and varieties of Lilies there is little to say, except that the very fine autumn was specially favourable to *Lilium speciosum* and the latest flowers of *L. auratum* in the open ground. Last season the importations of *L. auratum* and the other Japanese kinds did not suffer, as many thought, from the

war between China and Japan, and good bulbs were as cheap as ever. In many places, too, they yielded a grand display, but, on the other hand, in too many gardens they suffered greatly from the mysterious disease which often plays havoc with the golden-rayed Lily. The importations are this year later than usual, for in 1894 the first sale of *L. auratum* took place on October 24, and the year before that October 19, and now, November 14, the date of the first sale is not yet announced, while singularly enough a quantity of Japanese bulbs of *L. longiflorum* were disposed of in the London auction rooms as early as October 9, though in previous years bulbs of this kind never reached here before those of *L. auratum*. The flowers of the Japanese *L. longiflorum* are very superior to those of the ordinary kind as grown by the Dutch, and they yield a magnificent display when planted out in the open ground. Year by year the flowering season of *L. Harrisii* seems to be spread over a longer period, and at a meeting of the Royal Horticultural Society, held on October 15, a group of well-flowered examples was contributed by Messrs. Veitch.

A novel feature in connection with this class of plants was the holding of a Lily exhibition at the Botanic Gardens, Manchester, from October 22 to 26. Though successful, it was certainly far too late, as but few Lilies were to be had in bloom at that period, but as a set-off they included the showiest of all for pot culture, that is the several forms of *L. auratum* and *L. speciosum* in its innumerable varieties. While the bulk consisted of these, other kinds represented were *L. Batemanianæ*, *L. Leichtlini*, *L. Henryi*, *L. nepalense*, *L. longiflorum*, and some Tiger Lilies. Had the exhibition been held nearly two months earlier, a far greater collection of Lilies might have been brought together; still, then that invaluable kind for pot culture, *L. speciosum*, would have been absent unless forced, and then it is not nearly so attractive as when allowed to grow naturally. Though somewhat earlier, much the same may be said of *L. auratum*. H. P.

#### GARDEN VARIETIES OF CLEMATIS.

The warm, bright weather, of which we have had so large a share during the present autumn, has caused the different garden varieties of Clematis to be unusually free-flowering, and towards the end of October some of them were still very beautiful. Two varieties that have given great pleasure for months are the well-known *C. lanuginosa cordata*, whose very large pale-tinted blossoms are remarkably showy and admired by everyone. The second to mention is *C. rubella*, one of the Jackman section, and, like it, raised by Mr. Jackman, of Woking. The flowers of *C. rubella*, which are of a rich claret-purple colour, are not particularly large, but are borne in such numbers, and so continuously from July to the present time, that it must rank (at all events at this season) as one of the very best of all the varieties of Clematis. With the different species and garden varieties of Clematis it is possible to have flowers throughout the greater part of the year, for the various hybrid forms bloom from May to the present time—not the same varieties, it is true, but the members of one section succeed those of another, so that if a judicious selection of several varieties is made, some one or the other will be in flower throughout the time just mentioned. Of the different species, the Himalayan *C. graveolens*, with yellow flowers, is still blooming. After the autumn Clematises are over there is a lull for a time, but early in the new year, should the weather be fairly mild, the South Australian evergreen Clematis (*C. cirrhosa*) will produce its blossoms. The flowers are not particularly showy, being of a greenish white tint and covered on the exterior with a silky down. Individually they are rather less than an inch in diameter, but are borne in considerable numbers, and the setting of prettily cut, deep bronzy green leaves serves to form a very uncommon, but attractive winter picture. This species, which is

also known as *C. balearica*, was introduced into this country nearly 300 years ago, but it is very rarely met with. After this *Clematis* is past, one of the next to unfold its blossoms is *C. montana*, a native of Nepal, from whence it was introduced in 1831. This species is now well known and deservedly popular, for it grows freely and blooms with the greatest profusion. Splendid examples of this may be occasionally met with in the immediate neighbourhood of London. While some hybrid forms of *Clematis* are grown in pots, *C. montana* is very rarely treated in this way, yet I have seen some very pretty examples forced prematurely into bloom. The plants had been trained around a few sticks, and, not being tied in too stilly, formed, when clothed with their pure white Wood Anemone-like flowers, very attractive objects, and that, too, at a time when their relatives out of doors were still wearing their winter garb. H. P.

BELGROVE GARDEN.

THE following is the detailed account of contents of Belgrove Garden during summer and autumn of 1894, with indications of contents in spring. The numbers of the beds correspond with the numbers of the beds in the plan.

(1) Dunrobin Bedder dwarf Fuchsia edged with silver bicolor-leaved Geraniums in ten named varieties. Bed is thickly edged with *Milla conspicua*

tirrhinum. (12) New annual *Linaria Hendersoni* ericoides. The bed is thickly edged with *Brodiea grandiflora*. (13) New pure white Antirrhinum Queen of the North with line of dark crimson variety down the centre. (14) *Papaver nudicaule* or Iceland Poppies in three colours—white, yellow and orange. (15) *Iris Kämpferi* in 30 varieties, carpeted with Tufted Pansy *Sylvia* in centre, surrounded with broad rings of Ardwell Gem and Duchess of Fife. (16) Clump of hardy *Crinum Powellianum* edged with several kinds of *Daffodils*. (17) *Nemesia strumosa*. The bed is thickly edged with *Anemone nemorosa alba plena*, and is filled with double Tulip *Mariage de ma Fille* for spring bloom. (18) Ten of the choicest *Daffodils* in cultivation—namely, De Graaff's fine seedlings, Mme. de Graaff, Glory of Leyden, Golden Vase, F. W. Moore and Cecilia de Graaff, and W. B. Hartland's Ione, Jennie Woodhouse, John Ridd and Lorna Doone, with clump of the fringed trumpet Irish *Daffodil* *Crom-a-Boo* in the centre. (19) Single tuberous *Begonias*, edged with the blue-flowered *Eritrichium strictum*. This bed is filled with 60 single *Hyacinths* in spring in four colours, planted in a central clump of 10 of one variety, surrounded with rings of the three others, numbering 12, 18 and 20 respectively. (20) Complete collection of Girdlestone's Tom Thumb dwarf *Dahlia*s in 13 named varieties. (21) *Phlox Drummondii*. The bed is thickly edged with *Colchicum autumnale flore-pleno*, and filled with single early Tulips in spring. (22) Pattern bed

(31) Double Stocks. Bed is filled with early single Tulips in the spring. (32) Same as No. 30, but edged with mixed Croci. (33) Crousse's double tuberous *Begonias*, edged with *Gazania splendens variegata*, and thickly bordered with *Anemone nemorosa alba plena*. The bed is filled in spring with 60 *Hyacinths*, arranged as in No. 19. (34) Same as 30, edged with *Anemone nemorosa Robinsoniana*. (35) New dwarf French *Marigold* *Croix de la Legion d'Honneur*. This bed is filled with single early Tulips in spring. (36) Same as No. 30, but edged with the golden variegated *Gazania splendens* and bordered with *Campanula garganica*. (37) Single tuberous *Begonias*, edged with pegged-down double Ivy-leaf *Geraniums*, and outside with double white *Colchicums*. This bed is filled in spring with double scarlet early Tulip *Imperator rubrorum*. (38) Same as 30, edged with *Crocus speciosus*. (39) Same as 30, edged with golden *Gazania*. (40) Dwarf trailing perennial *Phloxes*. (41) Tufted Pansies. (42) *Tigridia grandiflora* and *T. conchiflora*, edged with mixed Croci. (43) Same as 30, edged with *Campanula turbinata* and *Triteleia Stella*. (44) Double tuberous *Begonias*, edged with *Barnard's perpetual dwarf blue Lobelia*. This is filled with early single Tulip *Keizer Kroon* in spring. (45) Same as 30, edged with double Ivy-leafed *Gerania*. (46) *Souillard* and *Brunelet's hardy hybrid Gladioli*, with thick edging of *Milla conspicua* or *Triteleia uniflora*. (47) Same as 30, edged with dwarf blue *Lobelia* and bordered with

Plan of Mr. Gumbleton's garden at Belgrove, Queenstown, Co. Cork.

and filled with single early Tulips in the spring. (2) Named double tuberous *Begonias* carpeted with *Mesembryanthemum cordifolium variegatum*, edged with dwarf blue *Lobelia Die Schöne Darmstaderin*. This bed is filled with *Proserpine* single early Tulip in spring. (3) Miscellaneous spring bulbs covered with an annual *Antirrhinum* in summer. (4) Named double tuberous *Begonias*, carpeted same as No. 2, edged with pure white dwarf bedding *Lobelia Reine Blanche*. Bed is filled with *Keizer Kroon* single early Tulip in the spring. (5) New named double tuberous *Begonias* in 30 varieties. This bed is also thickly edged with *Milla conspicua*, and is filled with early single Tulips in spring. (6) Five of the choicest and newest varieties of the dwarf *Gladiolus*-flowered *Cannas* raised by Pfitzer, of Erfurt, Crozy, of Lyons, and Kelway, of Langport. The bed is edged with the same dwarf Fuchsia as in No. 1, bordered with *Henderson's* sweet-scented Pansies. (7) *Lemoine's* hardy hybrid *Gladioli* of the *Lemoinei* and *Nanceianus* sections. The bed is thickly edged with *Colchicum autumnale il-pl.* (8) New *Echscholtzia Croix de Malte* and *Anthemis cupaniana*. Bed is edged with various forms of *Chionodoxa*, *Galanthus* and *Milla* for spring bloom. (9) Centre row of pegged-down *Coprosma Baueriana variegata*, surrounded with *Iresine Lindeni* and edged with dwarf *Ageratum Tapis Bleu*. The bed is filled with single early Tulips in spring. (10) Named double tuberous *Begonias*, edged with *Milla conspicua candida*. (11) Mixed *Phlox Drummondii*, edged with dark crimson An-

and filled with single early Tulips in the spring. (2) Named double tuberous *Begonias*, clump of *Lemoine's* scarlet *Lafayette* in centre, surrounded by rings of *Crousse's* Mme. Ernest Tourtel (creamy white) and *Ryder's* Pink Robert Browning, with border of double Ivy-leaf *Gerania* pegged down. The bed is thickly edged with *Colchicum autumnale flore-pleno album*, and is filled with early double white Tulip *Rose Blanche* in the spring. (23) Double named tuberous *Begonias* following a bed of double Stocks. This bed is filled in spring with early single Tulip *Keizer Kroon*. (24) Pyramid of variegated *Tropaeolum Lobbianum* *Spitfire*, edged with dwarf blue *Lobelia* and bordered with *Silene alpestris*. Each of these small round beds is filled with one variety of single early Tulip in the spring. (25) *Laing's* named double tuberous *Begonias*, with a few of *Mlle. Perrin's* and one of *Lemoine's* varieties, edged with dwarf golden-foliaged *Lobelia Goldelse*. The bed is filled with 60 single *Hyacinths* in four colours, as in No. 19. For the spring: (26) *Datura cornucopia*. This bed is thickly edged with *Seubertia*, or *Triteleia, laxa*, and *Caliprora lutea* for spring. (27) *Venidium calenduleum*. This bed is filled with early single Tulip *Couleur Cardinal* in spring. (28) Single specimen of double *Begonia* *Ryder's* Robert Browning, edged with dwarf blue *Lobelia*. (29) Yellow double tuberous *Begonias*, edged with a thick border of *Mesembryanthemum cordifolium variegatum*. This bed is filled in spring with early single Tulip *Duchess of Parma*. (30) Single specimen of double *Begonia* as in 28. The bed is thickly edged with *Brodiea grandiflora*.

*Aubrietia graeca variegata*. (48) Double tuberous *Begonias*, edged with dwarf blue *Lobelia*. (49) Same as 30, edged with *Camassia esculenta*. (50) Tufted Pansy *Sylvia* and other good sorts. (51) Same as 30, thickly edged with *Chionodoxas*. (52) Choice forms of *Tigridia lilacea, rosea aurea, alba, violacea, and Van Houttei*. (53) *Hymenocallis Deleuilii*, edged with dwarf blue *Lobelia* and *Silene alpestris*. (54) *Nemesia strumosa*. (55) Same as 30, with *Silene alpestris* edge. (56) *Lilium Martagon* var. *picturatum*, with *Campanula turbinata* round it. (57) Same as No. 9, but with blue *Ageratum The Zoo* round it. These beds are filled in spring with mixed early single Tulips. (58) New *Calceolaria* *Simon Durand* down the centre, dwarf *Victoria blue Cornflower* round bed, golden variegated *Cineraria maritima* at each corner, filled up with new *Papaver alpinum roseum* and variegated-leaved *Geraniums*. (59) Tufted Pansies of various good sorts. (60) *Montbretia crocosmiaeflora*, all best sorts. (61) *Salpiglossis grandiflora* in many varieties. (62) *Convallaria majalis*, undisturbed for forty-five years. (63) *Daphne Blagayana*, edged with an autumn *Crocus*. (64) *Senecio sagittifolius*, edged with *Anemone blanda alba* and other spring-flowering bulbs.

Along the whole length of the garden runs a broad border filled with hardy herbaceous plants, consisting of some *Tree Peonies*, the best perennial *Phloxes*, clumps of most of the best sorts of *Daffodils*, and edged on the side

next the garden with a double line of *Narcissus eystettensis plenus*, or Queen Anne's Daffodil. The chief feature of the end of this border near the house is a series of large clumps of the hardy hybrid *Crimmums*, consisting of *C. Powellii* type, deep rose; *C. Powellii intermedium*, pale pink; *C. P. album*, pure white; *C. grandiflorum*, *C. abyssinicum*, *C. pratense*, *C. yemenense*, and *C. Moorei*. Here are also established clumps of the fine Natal composite *Gerbera Jamesoni* and the giant Forget-me-not of New Zealand (*Myosotidium nobile*). As the chief feature in this garden in spring is the display of early blooming Tulips, it may be stated that about 3300 bulbs are planted about the middle of November.

W. E. GUMBLETON.

### NOTES ON PLUMS.

THE following notes on Plums which we are enabled to publish through the kindness of our correspondents will doubtless prove interesting to our readers. They are from all parts of the United Kingdom. The following are the questions which we submitted:—

1. *The value of the Plum as an orchard tree, and how far its culture deserves extension, and in what soils?*
2. *Your opinion as to the value of new Plums, including those of Japanese, American, or European origin?*
3. *The best flavoured Plums?*

The best Plums for flavour are Jefferson, Kirke's, Belgian Purple, Denniston's Superb, Coe's Golden Drop, and the Gages. For market the best early heavy cropping varieties are Rivers' Early Prolific, Czar, and Victoria, and for late use Monarch is deserving of extensive cultivation. In some seasons Plums have a good marketable value, but as to planting extensive orchards of Plums alone, I should be somewhat doubtful. In mixed orchards, with more than one string to the bow, good sorts might be planted, and in their turn be very profitable.—H. MARKHAM, *Moorworth Park, Maidstone*.

In reply to your questions on Plums, I regard the Plum as one of the most useful of hardy fruits, and its cultivation should be extended. It succeeds best in limestone soils, but most well-drained soils will grow it well. I think it ranks next to the Apple. New varieties have not been much planted in this district. The American varieties, Jefferson and Washington, are very good, but rather late as standards for this district. The best flavoured Plums are the Gages, viz., July Green Gage, Oullin's Golden, Reine Claude de Bavay, and Bryanston Green Gage. Good early varieties are Early Prolific Green Gage, Prince Englebert, and Kirke's. Good cooking varieties are Victoria (the best here), Pond's Seedling, White Magnum Bonum, Orleans, and Prince of Wales (a good variety, but the plants often die in this district). Denniston's Superb and Coe's Golden Drop are excellent dessert varieties.—BAILEY WADIS, *Birdsall House, Yorks*.

The Plum is not planted as an orchard tree to any great extent in this district. But where it is so planted it proves to be a fairly remunerative fruit to the planter. It is found to grow and fruit freely on most kinds of soil. But it is on the medium and sandy loams resting on chalk, and on the heavier calcareous loams resting on well drained clays or loamy gravels, where it makes the best and healthiest growth and bears the most abundantly. On the former soil the growth made is not so robust as on the latter, but the wood generally gets better ripened, and as a consequence the trees fruit more freely and constantly, and, as a general rule, the fruit is of better flavour. On the latter and heavier soil the fruit mostly attains to a larger size, and in sunny seasons is of excellent flavour.

On these soils the trees are apt, in the early years of their existence, to make too vigorous and sappy shoots, which, in dull seasons, do not get sufficiently ripened to ensure free fruiting, and this necessitates the too frequent labour of root-pruning and branch-thinning. The most reliable cropping kinds, and perhaps the most profitable to the grower on a large scale, are to be found among the cooking Plums, such as Victoria, Pond's Seedling, The Czar, Mitchelson's, Kirke's, Pershore, Emperor, and one or two others. The best-flavoured Plums are undoubtedly to be found among the Gages, such as Oullin's Golden, Transparent, Jefferson, Coe's Golden Drop (perhaps the best-flavoured Plum of any), Bryanston Gage, Denniston's Superb, and Reine Claude de Bavay.—J. KIPLING, *Knobworth Gardens*.

Our soil is very heavy, consisting of heavy loam and clay subsoil, but it is all drained a rod apart and 4 feet deep, and I consider that there is no orchard tree that will pay better than the Plum in this district (Apples excepted), for during my twelve years here the Plum has only failed me three times. I grow the Plum extensively as an orchard tree, and also on a west wall 85 yards long. Plums grown on the wall are earlier, larger, and better flavoured. I consider that the Plum deserves to be extensively cultivated in this district, provided the ground is thoroughly well drained. The soil most suitable for Plums is good, heavy loam. I prefer to grow the trees as pyramids. Green Gage, Coe's Golden Drop, Jefferson, Prince Englebert, Reine Claude Violette, Transparent Gage, and Kirke's are, I consider, the best-flavoured Plums.—W. SHEPHERD, *The Gardens, Greenwich, Dorking*.

Plums thrive well here and are very prolific, especially where the soil is not too rich, but with frequent root-pruning and liberal watering in dry seasons would prove a profitable crop. The best flavoured varieties are Green Gage, Jefferson, Coe's Golden Drop, Kirke's, Transparent Gage and Reine Claude de Bavay.—THOMAS WILSON, *Glamis Castle, Forfar*.

I should say the Plum as an orchard tree deserves extension, especially Victoria, which is as useful a variety as any to meet all requirements. We can generally look forward to a good crop of Plums provided we escape the late spring frosts, the soil being of a good loam and not on too cold a subsoil. I find that Jefferson, Coe's Golden Drop, Kirke's, Impératrice, Orleans and Green Gage do best with us; these are on walls, and Victoria does best on standards. The old Wine-sour I find very useful for preserving and cooking. Coe's Golden Drop is an excellent Plum for us, as it keeps a long time after being gathered and cannot be improved in flavour. In my opinion Green Gages should be more grown, as they are a useful fruit and much appreciated by rich and poor.—G. M. KNIGHT, *Park Gardens, Alfreton*.

The Plum succeeds as a standard in very sheltered positions, and I have seen this season as heavily cropped trees in East Lothian as are to be found in the south of England. It is doubtful, however, if it will succeed as an orchard fruit sufficiently well to pay. Plums thrive and fruit well on our light, open soil. I have tried a number of new Plums, and I consider The Czar to be the most meritorious early sort, and as a late kind Monarch is even better. The best flavoured Plums that I am acquainted with are Coe's Golden Drop, the Gages, and Jefferson. Dark-skinned varieties are less richly flavoured, and the best of these is Kirke's Black.—R. P. BROTHERSTON, *Tynningham, East Lothian*.

I have seen no Plum cultivated in Scotland which would induce me to begin orchard culture for profit. Compared with those in south, east, west, and midlands of England they are almost worthless. Victoria is the variety most often seen in cultivation away from walls, and seldom more than third-rate. I have seen no new Plums in Scotland outside or under glass to compare for quality with Kirke's, Jefferson, Coe's Golden Drop, and Green Gage. In damp seasons, Plums, like Apricots, are apt to split. The best-flavoured

Plums are those stated above, and grown on walls only.—M. TEMPLE, *Carron, Stirlingshire*.

I have tried Plums as orchard trees for several years, and consider them very uncertain. I would not in this district advise them for orchard crops. The only new Plums I have tried are Grand Duke, Czar, and Archduchess. I do not consider them so good as older varieties. The best flavoured Plums are Green Gage, Jefferson, and Golden Drop. The most useful and prolific Plum in this district, I consider, for a garden is Victoria.—EDWARD TATE, *Balcarres, Fife*.

As an orchard tree where the Plum thrives I should say it would be remunerative if the ground was cultivated between, and bush fruit or vegetables grown underneath. The situation should not be too low, or the trees would suffer when in bloom from spring frosts. I think the culture should be greatly extended and encouraged, as the fruit can be used in so many ways, and owing to the number of good varieties, if a judicious selection is made, they may be made to cover a period of three months at least. I have not come across a soil that would not grow Plums. Even in the poor soil of the Bagshot sand formation they thrive well and fruit freely if the soil is well trenched and fairly manured. For flavour there is nothing to beat the Green Gage and Coe's Golden Drop, Purple Gage, Ickworth Impératrice, Jefferson, Kirke's, Denniston's Superb, Bryanston Gage, in fact, all the Gage varieties, are good.—R. LLOYD, *Brookwood Asylum, Brookwood, Surrey*.

The Plum as an orchard tree in the north is useless. The only exception is the Damson, which occasionally gives good crops. The Plum in the north requires a wall, and where this is afforded, other conditions being suitable, it well repays cultivation. Early Rivers is a very useful early Plum, excellent for cooking and preserving, a great cropper, and some of the best fruit when well ripened may be used for dessert. The kinds I find most useful and which do best here are Denyer's Victoria, Oullin's Golden, Lawson's Golden Gage, Denniston's Superb, Magnum Bonum, and Coe's Golden Drop. I have tried Kirke's and Jefferson, but they do not do well here; they seem to require warmer summers than we usually have. I used to find these two kinds do well in the midland counties of England. Lawson's Golden Gage is one of our best sorts for dessert. It is an old kind, of medium size, deep yellow, and speckled with crimson next the sun, juicy, and nicely flavoured. The tree is hardy and robust. This fine old kind deserves to be more extensively planted; it is still one of the best for out-door culture. The Green Gage is no doubt still our best flavoured Plum, but in the north it does not bear very freely. Denyer's Victoria is perhaps the best cropper, and when well thinned out and well ripened the best fruits may be used for dessert. Denniston's Superb is a useful Plum, of fine flavour, and comes into use here about the end of August. Oullin's Golden is a useful early Plum, excellent for dessert, and in use about the same time as Denniston's. No doubt some Plums do better than others in certain localities, but those mentioned above are, I find from experience, the kinds which do best in this district.—D. MELVILLE, *Dunrobin Castle, Sutherland*.

As to the value of the Plum as an orchard tree in this locality, my opinion is that it would not pay, neither the climate nor the soil being suitable. As far as my experience of, now forty years, goes in Ross-shire and Inverness-shire, the only Plums that will prove at all profitable are the Victoria and the old variety of Damson. The best flavoured Plums I have are Jefferson, Green Gage, and Coe's Golden Drop.—KENNETH STEWART, *Dochnair*.

Our heavy clay subsoil is not favourable to the profitable culture of the Plum, and only a few hardy sorts can be depended on for regular bearing, such as Victoria, Diamond, Belgian Purple, Rivers' Early Prolific, Orleans, Jefferson, and Farleigh Prolific Damson. Our best flavoured Plums are Green Gage, Denniston's Superb,

Kirke's and Peach. The Plum seems most at home when growing in a good porous loam, resting on a gravel subsoil.—THOS. LAMBERT, *The Gardens, Burton Constable, Hull*.

The Plum as an orchard tree is certainly indispensable not only for cooking, but for dessert also. The Green Gage, Kirke's, and Coe's Golden Drop are valuable sorts, and should be grown extensively, according to the requirements. As a common Plum, suitable under almost any condition of growth, the Victoria, in my opinion, is superior to all others. A good loam is unquestionably the best kind of soil, and when planted on situations somewhat elevated above the valleys, the risk of loss from spring frosts is to some extent avoided. Orchard trees should be allowed to develop a good natural growth, more especially when they are planted in deep rich soils.—GEO. THOS. MILES, *Wycombe Abbey, Bucks*.

I consider the Plum a valuable tree for the orchard. During the last few years I have planted hundreds on very heavy soil and the result is good. The best new Plums I am growing are the Czar, Curlew, and Monarch. They carry good crops, and are very useful for sale or jam. The best flavoured Plums are Jefferson and the Gage Plums.—WILLIAM PLESTER, *Elsenhall Hall*.

The value of the Plum as an orchard tree depends more on the selection of the most suitable varieties than on any question of soil to all kinds of which, provided it is of fair quality and depth. Plums seem well able to adapt themselves. The trees grow most freely and last longest in a soil naturally moist, but this being most commonly found in low-lying places, there is always a great danger of injury to the flowers by frost in such positions, and a site of good elevation and sloping to the west would be more likely to make Plum growing profitable. In such places the culture deserves extension, as I find that the price paid for good Plums in the local market is generally remunerative, and in seasons of scarcity it runs high. The best varieties grown here, under purely orchard culture, are Belgian Purple, Orleans, Victoria, and Belle de Louvain; the last is one of the finest looking Plums in existence. It never splits with the wet, and it will keep for days after ripening if picked when dry. These qualities combined with its size and colour, make it the most suitable of all Plums for marketing, while in flavour it is decidedly superior to most cooking varieties. Both this and Victoria are heavily laden with fruit this year, and have had to be propped up to prevent breakage. The orchard culture of Green Gages is not profitable here, for what with spring frosts and the bullfinches good crops are much rarer than total failures. The old Prune Plum of the west of England orchards should be tried, as it is a most profitable variety where it does well. I do not meet with it in this neighbourhood, and whether it has been tried or not I cannot say. Neither Kirke's, Coe's Golden Drop, nor Washington succeed in the orchard; the two former have proved bad growers here, and the latter, though it grows freely enough, is a light cropper. A list of the best flavoured Plums grown here would include Green Gage, Huling's Superb, Jefferson, Kirke's, Reine Claude de Bavay (this only in a fine season and grown on a wall; I find it useless in the orchard), Coe's Golden Drop (when allowed to hang late), and Angelina Burdett, and to these I would add Denniston's Superb. These varieties should bridge the Plum season.—J. C. TALLACK, *Livermore Park, Bury St. Edmunds*.

The Plum is cultivated extensively in this neighbourhood by landlord, farmer, and cottager alike, but although the crops are generally good, bad markets bring its value as a fruit to a low level. The geological formation is limestone, yielding a heavy loam inclined to clay. In this the Plum luxuriates, and if the plants (bushes or standards) are allowed unrestricted growth, heavy yields are obtained the second or third year after being planted. Some trees I planted four years ago are now carrying several stones of fruit each. If heavy loam can be found in the vicinity of good markets, nothing, I am convinced, would be more

profitable than free-bearing varieties of Plums. My experience of new varieties is very limited, and the plants I have are too young to enable me to form an opinion of their value as fruit producers. For flavour, Reine Claude de Bavay takes the first place; Coe's Golden Drop, Jefferson, the Gages, Kirke's, and Victoria are good dessert in the order of merit given, and, besides, all are fairly prolific sorts.—J. RIDDELL, *Castle Howard Gardens*.

The value of the Plum as an orchard tree is very great, and in my opinion Plum-culture requires extension. In my younger days I lived in the noted Pershore Plum district, and had a good insight into the value of the Plum as an orchard tree. The chief drawback in those days was heavy gluts of fruit. This was caused through a very limited number of varieties being grown, early and late kinds not being sufficiently cultivated. The best soil is a light loam, and if heavy it must be well drained. In planting orchard trees it is advisable to get a suitable stock for the soil, as on some stocks the trees only fruit sparingly and make gross growths. Doubtless a trial of varieties on a small scale would be advisable before planting orchards of these fruits. In Worcestershire and Herefordshire immense quantities of Plums are grown, but mostly such kinds as Pershore Egg and Gisborne's. Doubtless the soil would grow choicer kinds equally well. Such varieties as Rivers' Early Prolific was a great gain to large growers, as this kind, though small, is in advance of others, and being a good cropper, rarely failing, is more valuable. For flavour I still think many of the old kinds difficult to beat. The old Green Gage still heads the list, this being one of the best flavoured fruits grown. Guthrie's Gage is also good. One of the best of the dessert kinds is Jefferson, a valuable wall Plum and a good cropper. McLaughlin's Gage is also worth mention for good flavour. Reine Claude de Bavay, Transparent Gage, Kirke's, Late Rivers, Coe's Golden Drop, Lawson's Golden and Ickworth Imperatrice for late use are all noted for good flavour. There are others of larger size and more showy, but the above are the best in this soil.—G. WYTHES, *Syon House Gardens, Brentford*.

The Plum here as an orchard tree I consider valuable, and its culture deserves extending. Near here Plums mostly do well and crop heavily. New varieties I have had no experience with. The best flavoured are the Gages, Washington, Jefferson, and Coe's Golden Drop.—WM. ANDREWS, *Tregothman, Cornwall*.

Plums where planted have been very profitable, Denyer's Victoria and Magnum Bonum being most grown and inquired for. Damsons fruit heavily; the soil is a heavy loam with clay subsoil. I have not had much experience of the new ones, except Grand Duke, which I think will be more grown as its merits become better known. Coe's Golden Drop is the best flavoured, then follow Green Gage, Jefferson, Washington, Oullin's Golden Gage, and Kirke's.—J. D. NAUSCAWEN, *Whiteway, Chudleigh*.

The Plum succeeds here admirably as an orchard tree; the soil, a strong loam, on the lias formation. The trees grow to a large size, bearing heavy crops in favourable seasons. Both here and in the adjoining Evesham district there is a large acreage of Plums, which is being yearly increased. The best for flavour I know are Transparent Gage, Jefferson, Golden Drop, Kirke's, Violette Hative, Rivers' Early Prolific, and Czar.—J. CLEARE, *Toddington, Winchcomb*.

I find the Plum as an orchard tree more productive and less liable to disease than Apples or Pears on light black sandy soil. The varieties I am growing in quantity are Victoria, Pershore, Diamond, and Rivers' Early Prolific. I wish I had more of the last-named, a sure bearer and good all round. I consider Kirke's, Violette Hative and Green Gage when properly ripened the best Plums. Unfortunately, Kirke's is not a free bearer.—ROBERT MAHER, *Yattendon Park, Newbury*.

The value of the Plum as an orchard tree cannot well be over-estimated when suitable varieties

are planted in good loamy soil, inclining to be heavy rather than otherwise, and resting on a gravelly subsoil, and protected from the north and east by a row or two of forest trees—say Spruce—sufficiently high to afford the necessary protection to the trees when in flower from cutting winds. As yet I have not had any practical experience of the Japanese and American Plums. I can, however, speak highly of Archduke, Sultan, Grand Duke, Belgian Purple, Early Prolific, Monarch, The Czar, Diamond, Pond's Seedling, and Victoria for walls, and for the same sheltered situation the following dessert varieties: Old Green Gage, Guthrie's Late Gage, Jefferson, Kirke's, Denniston's Superb, Bryanston Gage, and Coe's Golden Drop. Of Damsons last August I saw young trees of Shropshire or Michaelmas Damson bearing immense crops of fruit. As regards the best flavoured Plums, I have yet to learn the name of one that will come up to, not to say beat, the old Green Gage.—H. W. WARD, *Longford Castle, Salisbury*.

The Plum in this district would be valuable if cultivated more largely, but then the drawback would be a really good market for the fruit. The Victoria is grown most extensively, and is the most popular. Magnum Bonum and Orleans also are largely grown, and seldom fail to give a good crop. The soil is a retentive loam, with subsoil of green and yellow sand, chalk and brash. Denniston's Superb, Coe's Golden Drop, Green Gage, Jefferson, Purple Gage, Peach Plum, Reine Claude de Bavay, Kirke's, Angelina Burdett are, I consider, the best flavoured varieties I have. All these are good with me, and seldom fail to give a good crop.—W. A. COOK, *Compton Bassett, Wilts*.

Plums answer admirably on our light sandy soil, resting on the old red sandstone, and their culture might with advantage be considerably extended about here, proving that the trees will crop freely on light soil as well as on a heavy one. At the same time I strongly advocate the bush system of growing Plums, as they pay the best and quickest. One year I realised £176 from an acre of Victoria grown as bushes. Neither the Japanese nor American Plums have been quite satisfactory here yet. Of the former, Satsuma has done the best, and Mariana of the latter. Amongst new European varieties, Monarch, Archduke, Late Transparent, and Smith's Purple Prolific have proved decided acquisitions; the two first and the last named should prove valuable market Plums, and are worth a place in every garden, large or small. Grand Duke also promises to be of sterling merit. I think the following varieties possess the best flavour: Golden Transparent and Oullin's Golden Gages, Jefferson, Kirke's, Coe's Golden Drop, Huling's Superb, and the old Green Gage.—S. F. WRIGHT, *Gleewston Court Gardens, Ross, Hereford*.

The Plum is not much cultivated around this district as an orchard tree, so I cannot speak as to its value in that respect. The Victoria, Magnum Bonum, Red and even the old Green Gage do well as standards in a cottage garden near here, that being the only case I know of. The soil around here is a very sandy loam with a subsoil of sand. The following I consider the best flavoured Plums: Belle de Septembre, though classed as a cooking one, is excellent for dessert when quite ripe, Coe's Golden Drop, Denniston's Superb, Green Gage, Jefferson, Reine Claude de Bavay, and Bicton. I cannot speak about new varieties of Plums.—J. MAYNE, *Bicton*.

The Plum is admirably adapted as an orchard tree, and it certainly deserves extension under this form if a market could be found for the fruit. The Plum would be more fruitful than it is in some gardens if grown as a standard than as a bush. Under this latter form so many people cut or prune the trees in too much to ensure good crops of fruit, whilst with standards this would not be the case. Nor do the trees grow exceptionally large. After the first year or two, when the tree has to be pruned to get it into shape and so form a well-balanced head, strong growth is checked, and the tree produces short, stubby growth

studded with fruit blossom. It is only when the trees are kept cut in and grown in loose, over-matured soil that they form gross, unfruitful growth. Treated to a firm root run, the surface not being dug, and with suitable soil, the Plum is sure to succeed. A well-drained, sandy loam, where a fair proportion of lime is present, will grow Plums well. The Plum also succeeds well on limestone or calcareous soils. It must have free exposure, and not be planted under the shadow of forest trees. As regards our new English-raised varieties, Monarch is the latest new variety that I am acquainted with. This is well worth extended culture, having proved itself to be a most valuable cooking Plum, coming into use after most other varieties are past. For flavour I give the preference to Jefferson, Oullin's Golden, Green Gage, Denniston's Superb, Purple Gage, Coe's Golden Drop, Kirke's, De Montfort, Ickworth Impératrice, McLaughlin's Gage and Angelina Burdett. As the best six varieties I should select Jefferson, Oullin's Golden, McLaughlin's Gage, Green Gage, Kirke's, and Coe's Golden Drop.—A. YOUNG, *Abberley Hall Gardens, Stourport.*

### THE HEXHAM NURSERIES.

HEXHAM, an old northern town, has a long and eventful history bound up with the perpetual Border warfare of centuries gone by. It is now a centre of considerable activity, being about midway between Newcastle and Carlisle, and the chief market or distributing centre of the products of the rich Tyne valley. Here about a century ago was started by Mr. Robson the nursery that in latter years Messrs. Fell have so greatly extended till it embraces most branches of the nursery trade, special prominence being given to the raising and distribution of forest trees, which we saw in great numbers in their several stages, from the tiny seedlings to the young, sturdy clean-grown specimens ready for the present planting season. The ground devoted to these is at a considerable elevation above the town, and naturally ensures a hard and healthy growth. Lower down this hill is a large area devoted to fruit trees and Roses, where we noted enormous breadths of the now popular Whinham's Industry Gooseberry, which originated in this county at Morpeth. The trade in this particular kind is enormous, and is growing still. The stock for this season's distribution from here alone total 200,000, and out of this number orders have already been booked for 150,000. In the district as well it is largely grown as a market fruit, in an average season about 50 tons of this variety being despatched from Hexham. The Hesse Pear, too, is another popular market kind extensively grown in the district, as many as 80 tons of it having been sent off in one season during recent years. Our attention was drawn to a large breadth of a new Plum stock, which having proved satisfactory in a small way is now undergoing an extensive trial. It is an American wild, or half wild, Plum named Mariana, and resembles the Cherry Plum somewhat in style and appearance of growth and fruit. Plums worked upon it commence bearing in their second year, Rivers' Early being most noticeable in this respect, as it carried quite a large crop. A point that will tell still more strongly in favour of this stock is that it strikes readily from cuttings.

Ornamental summer leafing trees, especially distinct varieties of our own native trees, receive much attention in this nursery. There is among them quite a number of beautiful forms that deserve more attention from planters who, unfortunately, generally ignore them, and plant instead very doubtful evergreens, with deplorable results. Willows for the water-side are numerous, and some of them rival the hardy Bamboos in lightness of cage and slender graceful growth, whilst others with highly coloured bark give, when well planted, a brilliant glow of colour during the dullest and darkest days of the year. Besides well known forms we saw a broad-leaved variety of the Babylonian Weeping Willow, its

weeping habit quite as pronounced as that of the old *S. babylonica*, but the leaves were altogether larger, both longer and broader. Another handsome variety is that named Wentworth Seedling. It is clearly a form of the Cardinal Willow, but Messrs. Fell say the colour of its bark is of a deeper red, which colour, of course, was not fully developed at the time we saw it. Poplars are extensively grown, and the new Canadian Poplar is highly praised as a town tree by Messrs. Fell, who planted Scotland Street, Glasgow, with it, and there it has grown splendidly. *P. Bolleana nivea* is also a good town tree, with large leaves of a leathery texture and white on their under-surfaces, though less so than those of the common Abele Poplar. *P. tremula pendula* we also saw. It has a wider branch-spread, and makes a more irregular, informal head than the variety that comes from the Continent under the name of Parasol de St. Julien. The old English narrow-leaved Elm, as growing here, is a pretty, small-leaved kind, worthy of note, and several varieties of Ash are deserving of mention, especially the

were shown a batch of the Venetian Sumach which was bought from America under some such name as "New Purple Wig Tree." Weir's Cut-leaved Maple is another charming tree, having a distinctly weeping tendency and deeply-cut leaves prettily adorning its long, slender branches. Among the *Pyrus* and *Sorbus* tribe, also well represented, we noted the Swedish Service Tree, which fruits freely, and has pinnate leaves terminated by a large entire leaflet. *Genista tinctoria elata* we saw a large group of, but just passing out of bloom. It is a tall form of the native Dyer's Weed, and well merits a place in gardens, as, like the type, it wants no special position, but is a brilliant and showy, late-flowering member of the Broom family. It grows 2 feet or more in height, and flowers profusely the entire length of the shoots.

In this northern district Messrs. Fell report considerable injury to the conventional garden evergreens. Even Lawson's Cypress suffered to a considerable extent, and not a few were killed outright. *Phillyrea vilmosiniana* did not prove hardy, but *Osmanthus ilicifolius* came through the cold untouched, and is likely to receive much more attention in consequence. Carnations also grow well at Hexham. We saw large beds of good self kinds planted in the open quarters. Hardy flowers, too, fill a considerable space, and when we saw them, Sunflowers, Coneflowers, Asters, and *Chrysanthemums* were still bright.

## GARDEN FLORA.

### PLATE 1041.

#### DAY LILIES.

(WITH A COLOURED PLATE OF *HEMEROCALLIS AURANTIACA MAJOR*.\*)

NOT many species of Day Lily are grown in gardens, but the few we have are all first-rate hardy flowering plants, and their blooming season is long-continued, commencing quite early in the spring and lasting till quite the end of summer, whilst it is by no means unusual for the early-flowering species to give secondary spikes during the autumn months.

*Hemerocallis aurantiaca major*, the subject of the coloured plate, is a new and most noteworthy addition to the Day Lily family. It is certainly one of the finest new hardy plants obtained within recent years. It was first shown this season by Messrs. R. Wallace and Co., of Colchester, at the R. H. S. meeting held at the Drill Hall on July 9, when the plant was awarded a first-first certificate. It is said to have originated in Japan, where it was first observed growing in a mass of *Iris Kämpferi*, which points to the possibility of its being a chance seedling, perhaps the result of an accidental cross. Whatever its origin, there can be no question as to its value and, above all, its great distinctness and rich colour. All the Day Lilies are plants of hardy and robust growth, and this desirable quality is, if anything, accentuated in the new kind under notice, which partakes most of the character of *Hemerocallis fulva* (syn., *H. disticha*), all the broad-leaved and more or less tawny-flowered forms being placed under this species as varieties of it. The flowers of *Hemerocallis disticha* are of an orange-brown colour, and a two-forked branching of the flower-spike is another characteristic of it, besides the extra broad strap-like leaves, which impart to it an aspect of rich luxuriance even in growth alone. All these distinguishing traits are readily apparent in the new kind now figured, and it there-

*Hemerocallis flava.*

entire-leaved variety (*Fraxinus monophylla*), which differs to such an extent from all other forms, that one might feel disposed to dispute its relationship but for the unmistakable proof furnished by its wood and buds. It is a rapid and strong-growing tree, and has large, broad, somewhat heart-shaped leaves, deeply serrated along their edges. The Walnut-leaved Ash is a fine form, distinguished, as the name would imply, by having leaves much like those of a Walnut, whilst *F. oxyphylla* is charming in an opposite way, its leaves being narrow, small, gracefully Fern-like, and of a shining glossy green as though polished. The Cut-leaved Ash, too, has a distinct appearance, and looks like a great Pteris Fern. A Birch lately bought in under the name of new American Cut-leaved shows marked affinity to what we grow as Young's Weeping, and in this respect complaint was made of the misleading character of several popular American names which have been coined and used to suggest new forms, which, when purchased, turn out to be things we have in abundance. Such reprehensible practices are opposed to fair dealing. We

\* Drawn for THE GARDEN by H. G. Moon in Messrs. Wallace's nursery at Colchester. Lithographed and printed by Guillaume Severeys.

15. ALL. AL. 12. 11. 11.

fore may be a seedling. The present name has been given to it by Mr. Baker, of Kew. In leafage this new kind is handsome, a decided glaucous tinge overlying the deep green body colour, and the two-forked flowered arrangement is also seen in the spike figured. The rich apricot colour of the flowers is also faithfully shown in the plate, but the first flowers having fallen, the one represented is not full-sized, nor does it show the great breadth of petal manifest in earlier blooms. The flowers open out widely, the petals reflexing to a marked extent, whilst they are of such surprising substance as to appear quite thick and fleshy. The flower-scape, too, is extra stout, holding the flowers boldly up above the ample tufts of arching leaves. The plant is now being distributed, and no doubt ere long will be plentiful in the gardens

among Chrysanthemums could hardly be found. The flowers are much smaller than those of most single-flowered kinds and of a delicate blush colour.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**SUCCESSIONAL CUCUMBERS.**—Where these were planted out in October, and are expected to afford a supply of fruit in January and February, when the actual winter plants are on the wane, great care and regularity will now be needed in their treatment. Beware of too much fire heat, as the short sunless days of December prevent the possibility of using the syringe to any extent over the foliage, and on this account red spider or

down, the plants suffering far less from partial darkness for a few hours than from the complete dispersion of atmospheric moisture brought about by high and arid winds. By this date growth will have proceeded some little distance up the main trellis and the side laterals will need a tie here and there to keep them in position, the great aim being to leave no more leaves than can be fully exposed to sunlight and air. These plants will show surface roots less frequently and in smaller quantities than the established winter fruiters; consequently top-dressings must be few and far between, it being much better for the general well-being of the plants that a few roots should remain exposed than by undue additions of loam to render the bed sour and unwholesome. Manure water must be applied with great judgment in winter, growth never being sufficiently stout and leathery to assimilate strong doses of liquid or liberal sprinklings of artificial fertilisers. The best way is to give the former of the colour of pale ale for the period of a fortnight, then to abandon its use for a similar period, resuming it again in due course, and where chemical manure is used to give a moderate surface sprinkling every three weeks. Liquid from the farm or stable yard should be clarified, as if thick it is apt to clog the border and do more harm than good. Keep up as near as possible a night figure of 60° in time of frost, allowing one of 65° when such can be maintained by mere lukewarmth in the pipes. Admit a little fresh air at 10 a.m. on warm sunny days and withdraw it at 1 p.m., damping the floors and walls with tepid water. In smoky districts wash the roof glass once in three weeks, and exercise patience until lengthening days and increased solar heat in January induce renewed activity and greater fertility. Should wireworm be troublesome, trap them by spreading fresh horse droppings over the surface of the border.

**NOVEMBER CABBAGES.**—If a sowing of Cocoa-nut, Wheeler's Imperial, or St. John's Day was made early in June, nice white heads will now be plentiful; these of course are of better quality than ordinary sprouts, the result of old spring Cabbage stumps being headed back, and their flavour will have been improved by exposure to early frosts. These had better now be used freely, as they will not stand a great deal of frost, particularly should such occur immediately after heavy rains, and using these will reserve the more hardy Colewort, which in mild weather will continue to increase in size even in December. The advanced condition of many spring Cabbages at the present time, owing to the extra warmth of September, plainly indicates the folly of sowing early, especially in warm gardens in the home counties. Mine were not sown till the very end of July, and they are too large and sappy to please me. Some gardeners check growth at this date by thrusting in the spade close to the plant, thereby severing the roots low down, but I sometimes think that the remedy is as bad as the disease. Where this is done the soil must be well firmed round each plant afterwards.

**SOWING TOMATOES.**—Those who wish for an early crop of Tomatoes, and have not by them a batch of plants raised from cuttings, may sow now, using small pots in preference to pans, and putting about three seeds into each, finally drawing out all but the strongest plant. Keep in a temperature of 60° close to the roof-glass, and be very sparing in the use of water both before and after germination, as Tomatoes in a young state are most impatient of moisture at this season. These if well attended to and kept stocky will bear fruit at the end of March. On no account use the syringe overhead, as this often causes the young seedlings to damp off wholesale.

**COVERING GLOBE ARTICHOKEs.**—The somewhat severe frosts which have already occurred should remind us of the necessity of protecting the crowns of this popular vegetable. Some gardeners do not believe in the practice, but the fact is that even on heavy soils Artichokes are safer with a covering, provided it be of a loose, shaggy nature. To mulch with farmyard manure in an advanced state of decomposition, as some do, is simply to

*Hemerocallis fulva fl. pl.*

of all those who grow the best hardy flowers. Flowers of it were also shown at succeeding meetings at the Drill Hall, thus proving its value for materially prolonging the season of bloom. Day Lilies are also useful for cutting, being pleasingly fragrant and developing their buds even in a cut state. The only other Day Lily that has been figured in THE GARDEN is *H. Dumortieri*, a plate of which will be found in Vol. xxxi., p. 280, accompanied by a good descriptive article of all the other kinds in cultivation.

**Chrysanthemum Miss Rose.**—A group of this single-flowered Chrysanthemum is one of the finest things to be seen at Kew now. The plants are dwarf, some of them not 2 feet high, and all veritable sheaves of bloom, completely covering and hiding the shoots. Anything more delightful

thrips must not be allowed a footing. Some growers fancy that a brisk heat from hot-water pipes is necessary in winter in order to atone for the deficiency that is produced by the sun's rays, but it is a fact that winter Cucumbers suffer less soon from a low night temperature than do plants which do their work in spring, when bright sunshine raises the mercury to 85° or 90°. Where the plants are located close to the hot-water pipes it is a good plan to cover the latter with strips of common list or even old portions of garden mats, and to soak them daily in order to modify the heat at that particular point, and thereby lessen the liability to insect attacks. Where the roof is furnished with roller blinds they must now be brought into use, especially on cold windy nights, as these if composed of good stout material are the best possible economisers of fire heat the Cucumber grower can have. On stormy days I have sometimes allowed the blinds to remain

court disaster, as this soon becomes soddened, and in the event of severe and long-continued frost, is converted into an icy mass which is bound to paralyse, if not finally ruin, the crowns and roots. What I advocate is a good covering just now of dry Bracken, or, failing this, light strawy litter, working it well in amongst the remaining growths, renewing the covering again in January. Where so many err is in postponing covering until frost has actually injured the crowns, which is done far sooner on heavy soils than many people are aware of. In low-lying situations where Artichokes winter badly the safest plan is to sever a number of young side growths in autumn and pot them up, keeping them in a somewhat dry, airy pit, where a covering of litter can be given in case of severe weather. Let the pit be free from drip and keep the lights tilted over the plants, as if rain soaks into the centres it very often causes rot in a short time. Potting up of the crowns ought always to be done in October, but where, through pressure of work, time could not then be spared it is not yet too late. Jerusalem Artichokes should now have their growths cut off a few inches from the ground, as although these usually grow in an unimportant part of the kitchen garden, the stems and withered foliage are anything but attractive. Let none but the best shaped tubers be saved for seed, this being the only way to keep the stock select.

**EARLY SEAKALE.**—It is now high time all who wish for Seakale in fairly good time should get a batch of crowns into warmth. There is really very little gain in trying to push badly ripened crowns unduly, as they are very obstinate and the produce is weak and watery. Seakale this season made a prolonged growth owing to the September heat following rain. Those who acted according to advice given in spring and planted a sunny border with thongs for early work will now reap the advantage. No better place can be chosen than the Mushroom house, where in a temperature of 55° the growth is sturdy and the flavour good. I have a bricked-in space between two beds where I bring on the first two batches, boards being laid over the top to husband all the heat possible. I find that the warmth from the two beds urges the roots into activity in a minimum of time. Those who require a dish or two specially early may accomplish their object by putting half a dozen crowns in a 12-inch pot and placing them over the pipes in the Pine stove or similar warm structure, well soaking the soil and covering with inverted pots and old bags. It will be well to lift a good quantity of crowns now and to lay them in behind a north wall, covering them with 6 inches of leaf-mould. This preparatory process ensures a quicker growth when placed in heat. The Lily-white is certainly finer than the old variety, but in my opinion does not force quite so readily in the early part of the season. Its colour is very taking when dish-ed up. I always soak the Seakale with warm water after being plunged, and keep it sufficiently moist by overhead syringing every other morning. This process also keeps the crowns nice and moist, and the steam engendered therefrom is helpful to growth.

**MINT.**—This may be thought an early date for boxing Mint for forcing in Peach houses and vineries, but I find that by so doing it gets well established in the soil before being started into growth, and that the latter is in consequence more abundant. Plant in fairly deep boxes, as it is a very free rooter, and when limited for root room soon gets starved and grows weakly. Mix a fair amount of good rotten manure with the soil when boxing it.

J. CRAWFORD.

### FRUIT HOUSES.

**POT VINES.**—The season for ripening the Vines in pots was all one could desire, and no time should be lost in starting them so as to get ripe fruit early next May. If the canes are home-grown, the cultivator will ere this have prepared them for early planting. If purchased, there should be no delay in selecting the same, preference being given

to short-jointed, well-ripened wood. For general culture I do not think the Hamburg can be beaten as a good forcing black variety, and Foster's Seedling as a white, the former being the more reliable. Many growers have to use structures not well adapted for early forcing, but in all cases a small pit or low span-roof is most suitable, as later on, when the fruit is setting, we may expect severe weather, and every ray of sunlight will be necessary to get perfect fruit. By growing Vines in pots, hard forcing may be resorted to, the Vines being worthless after forcing. I admit a second crop can be secured, but young plants are most reliable. Of late years I have grown fewer Vines in pots, planting out the canes in narrow borders. By this means I have secured more bunches with less trouble in watering, and the treatment is much the same. I find, however, that the pot Vines break sooner, so that for hard forcing they are more reliable. In placing the canes in their forcing quarters, if the calendar advice (p. 263) was followed, no pruning will be necessary; indeed, pruning or shortening of lateral growths at this season will cause the Vines to bleed badly as soon as the sap begins to ascend. If pruning has been neglected, it will be better now to leave the canes full length and disbud later on to the required distance. Young canes will not need painting or much cleaning if free of insect pests, but if the least trace of mealy bug be on the Vines, wash thoroughly with tepid water and soft soap, with a small quantity of paraffin mixed with the soap to make it soluble. The roots should get assistance at starting, plunging the pots in a bed of fresh leaves and stable litter. This should be placed in a heap for a week or two previously and got into condition for plunging. In fresh material the pots should only be partially plunged at first, placing lower in a week or two and adding new material as the older sinks. Previous to introducing the Vines it is well to thoroughly cleanse walls and glass and make as neat as possible, and when the canes are in their quarters, to bend down towards the front of the house, giving each a sharp curve to induce the bottom buds to break freely. With heating material as advised, less syringing will be necessary, as the moisture from the bed will assist the Vines. Where there are only hot-water pipes, syringing several times a day will be necessary, but in any case the walls, floor, and beds should be damped over early in the morning and at mid-day to maintain a genial temperature. The thermometer may range from 50° to 55° at night, with 10° higher by day. Ventilation for some weeks need not be given, as a good rise of temperature during the day will be beneficial. Much the same treatment is necessary with Vines planted out. They, too, are greatly assisted by warmth at the roots when starting. Very little water at the roots will be required for a time in the case of pot Vines. A thorough watering with tepid water at the start will suffice for both pot and planted-out canes for some weeks, but when water is given it should be liberally supplied.

**EARLY PERMANENT FORCED VINES.**—These should be prepared for the start if ripe Grapes are wanted in May. Thomson's styptic should be applied to the cut portion of the canes before starting, as if allowed to bleed when breaking they lose vigour, and at that season bleeding is difficult to stop. The favourable season for ripening should tell on early forced canes, as the wood should be all one may desire. The end of November or first week in December is a good time to start, and Vines in good condition may get a temperature only slightly lower than advised for pot plants. In this matter the grower must take the outside temperature into account, as in mild weather hard-and-fast rules need not be observed. The same remarks apply as regards ventilation. Previous to starting the Vines it is well to examine the border, and as the earliest should be inside, moisture, if necessary, should be given at a temperature of 70°. This passing through the soil will soon be cooled down, and in all cases it is advisable to close the house a few days previous to watering. The Vines will be greatly benefited

if a bed of warm leaves and litter can be placed on the surface to start the roots. Watering should be done before placing the fermenting material in position. Outside borders are not advisable for hard forced Vines and are now rarely made, but in case the roots are outside, a good depth of warm material should be employed, and shutters or corrugated iron used as a top covering to throw off heavy rains or snow. Daily syringing as advised above and other similar details will be requisite, and it may be necessary to top-dress the borders with bone-meal or good yellow loam, much, however, depending upon the condition of the Vines. If hard forced, the aids named above can well be given later on if desired or in liquid form.

**MIDSEASON GRAPES.**—Pruning, cleansing and preparation for the season named will now be necessary in this department. The term may be applied to Vines which produce fruit from June to September. There is no gain in delaying pruning after the fall of the leaf; indeed, a long rest will be beneficial and the necessary winter work may be commenced, as if done now there is less fear of bleeding and the houses present a much neater appearance. All loose bark should be rubbed off old Vines, skinning being avoided, cleansing with soft soap and tepid water, and with a brush well working into the knotty portions of the Vines. Painting is also necessary, and the old, but reliable Gishurst compound is still one of the best insecticides mixed with a little clay to make it adhere to the rods. For mildew, add sulphur liberally to the Gishurst and well limewash the walls with fresh lime, adding sulphur also, as mildew, once it obtains a hold, reappears each season if not thoroughly eradicated at the winter cleansing. Where mealy bug exists, too much care cannot be observed at the cleansing, soluble paraffin being a safe remedy when carefully applied. I prefer to use it as a wash where it can be used in suitable quantities. In pruning these Vines it is not well to wait until the last leaf has fallen, as often at the points of the laterals the small late growths remain green. Hard pruning of certain kinds, such as Gros Colman, must be avoided, and in all such cases it is advisable to lay in new growths or leaders whenever possible. Young canes left last year should be shortened according to their strength, strong canes being dealt with liberally, the weaker ones cut back more. Borders should be top-dressed if necessary, taking away all loose surface soil, getting close down to the fibrous roots, and giving a dressing of rich compost in which bone-meal, mortar rubble, and wood ashes predominate.

**LATE GRAPES.**—This is a serious time for Grapes hanging. During wet days or foggy weather very little air will be required, and fire-heat will be necessary to dispel damp. In fine weather air freely, with warmth as advised, and give the Vines all the light possible by removing decaying leaves. At least once a week go over the bunches, removing all decaying berries. If other plants are wintered in houses with Grapes hanging, any watering required should be done early in the day. Water as sparingly as possible; in fact remove all plants unless they cannot be housed elsewhere. Grapes at this date often shrivel badly if the borders are kept too dry, and my remarks as regards moisture are not intended to convey that the Vines roots must be kept dry—indeed, the reverse. In case of dry borders give a thorough soaking as early as possible on a fine day to allow the moisture to dry up by nightfall, and ventilate freely during the day. Late large Grapes, such as Gros Colman, need more care than other varieties if at all thick in the bunch; indeed, they well repay removal of berries wedged into each other. Open bunches keep best, so that in cutting ripe fruit this should be considered. Outside borders in which Vines carrying late Grapes are should be covered with dry leaves or shutters. If the former, they must be merely put on as a protection against heavy rains. I do not advise decayed manure, the borders being better left uncovered than covered with wet materials.

G. WYTHES.

## KITCHEN GARDEN.

### PREPARING FOR WINTER.

WITH the leaves falling in such numbers all around us, we are forcibly reminded of the approach of winter, and should this visit us soon, let it not find us unprepared. There are many things that can be done while the weather is mild that may be of great service in forwarding work should severe weather set in at an early date. For example, some of the Asparagus beds from which it is intended to lift roots for forcing and from which the summer's growth has been removed ought to have a dressing of littersy manure or half-decayed leaves placed over them to the thickness of about 9 inches to ward off the frost. By so doing much inconvenience is avoided during a long spell of severe weather, as the roots can then be lifted at any time when required, for it is seldom that frost penetrates far into such material. Where the ground is stiff, and therefore very retentive, this covering will prevent the rains from making it pasty, so that digging may be proceeded with as soon as the roots are lifted. Rhubarb has now shed its leaves; that intended for forcing may therefore be lifted and stored close together, covering the roots sufficiently with litter to ward off any frost. By so doing there will be but little difficulty experienced in being able to get them at any time they are required for placing in the forcing house. Seakale will soon be shedding its leaves, and the roots may be lifted and laid in on a north border and afterwards covered with litter of sufficient thickness to ward off the frost. I find Lily White the best for early forcing, as it grows much more quickly than the old form. To have this vegetable of the finest possible flavour, it should be grown without the aid of fire-heat; therefore those who require early supplies should take up roots as soon as the leaves separate freely from the crowns and plant them thickly in a warm cellar. Here they will grow gently, the growth being both crisp and tender. Rhubarb also forced in this way is far more tender than that grown more quickly in heated structures. A portion of the crop of Chicory should also be taken up and prepared ready for introducing into a place to blanch.

Many people lost their Globe Artichokes last spring owing to the severity of the frost, and those saved were so injured in many instances that it took the whole summer for them to recover. It may be well, therefore, to remind such of the necessity of being well prepared by the time frost sets in. Globe Artichokes are not difficult to grow provided they are treated properly. Not being perfectly hardy in this country, they need protection during winter, particularly on cold, heavy ground where the frost penetrates to a far greater depth than it does on light, sandy soil. Material ought to be at hand in readiness in case frost should set in. If the ground between and round the plants is covered with leaves to the thickness of about 6 inches, it is seldom that frost will harm them. On the first approach of severe weather the roots also should be covered with rough litter to prevent the ground underneath them from getting frozen. It does not much signify about the foliage being killed so long as the hearts of the suckers are kept alive, as leaves will soon be produced again on the first approach of warm weather in April. Any one desirous of having an early supply may take off some of the suckers at the present time and plant them in pots, growing them on in a frame through the winter and planting out in spring. The stems of Jerusalem Artichokes

may now be cut down, and after lifting a supply for present use, the rest should be covered with litter of some kind to prevent the frost from penetrating the ground that future lots may be lifted as required during wintry weather. I have always found that these, Parsnips, and Turnips are much more appreciated when lifted fresh. Lettuce in the open ground that are large enough for use ought to have some boards placed round them to form a temporary frame on which to rest the lights when the first approach of severe weather presents itself. Where these cannot be afforded, sticks bent over the beds to support mats or canvas covers will be found to answer very well, as they will ward off 10° or 12°. So far the present month, with the exception of two days, has been wet, and more than 2½ inches of rain has fallen. Others who are situated in positions like myself where the ground is heavy will understand the advantage of having all vacant ground dug as opportunities present themselves. I do not advocate getting on such land in wet weather; neither do I advise digging where it is intended to sow very early crops, for the looser such ground lies at this time of the year the more moisture will it hold. But where sowing or planting is deferred till the end of March or early in April, then I recommend that the ground be thrown up roughly, in order that frost and air may penetrate as deeply as possible.

H. C. P.

**Tomato Yellow King.**—I have grown this variety this year and find it an excellent cropper, the fruit of rather delicate flavour, flesh firm, and juicy. It is a wonder the yellow-fruited kinds are not more generally grown. It has been said that they do not crop well, but I have found this kind quite up to the average, each fruit weighing from 10 oz. to 14 oz.—W. H. S., *Comberford Hall, Tamworth.*

**Potting Cauliflower plants.**—The old method of potting up a number of Cauliflowers for early March planting has much to recommend it, as, though plants raised in heat early in the year will be a little later than the autumn plants, the latter have more size. Even a short time in May, at a season vegetables are scarce, is of great value to the cultivator who has a large supply of vegetables to provide. I admit there are at times serious losses if the plants are not placed in frames, but much depends upon the way they are sheltered, also the material potted up. Short, sturdy plants should be selected and no coddling in fine weather given. The plants will stand much exposure if grown thinly from the start. Damp is equally as injurious as frost, so that a dry place is important. Having a great quantity of vegetables to supply in the early spring, I find the potted-up plants most reliable; they can be planted out without shelter in March and earlier in mild winters. By sowing in heat a succession is maintained.—G. W. S.

**Large Carrots.**—I was glad to see "A. D." (p. 376) drawing attention to this subject, for the prevailing idea now-a-days is to have everything large, and in many instances at the expense of quality. Large flowers, large fruit and large vegetables seem to be all the rage. No doubt we all admire well-grown specimens of all kinds, and if these have quality combined with size, there is no reason why preference should not be given to them, but how seldom is this the case. It is more the exception than the rule to find the largest specimens having the finest quality. Formerly it was a rule with gardeners to sow Carrots some time during the month of April to produce roots for lifting and storing for winter use. In all well-cultivated gardens this idea, however, no longer finds favour, for the roots produced from such sowings often split, owing to heavy rains in August, particularly on heavy soil, the greater portion of the crop being thus rendered useless. Instead of sowing the main crop in April I now sow in June, and for a late supply towards the end

of July. I am well aware that such late sowing would not answer in all places, but where large supplies have to be obtained from a limited space and two crops can be taken instead of one, there is certainly a great advantage, and under good cultivation roots sufficiently large for the requirements of a gentleman's table can easily be obtained if the quick-growing kinds are sown. New Intermediate, Matchless and others of that class are far more useful than some of the older forms if the seed is sown during the month of June, and may be relied upon to give general satisfaction where others fail, even in districts where the Carrot fly and wireworm are troublesome.—H. C. P.

**Savoy Cabbages.**—So unduly early do we as a rule sow seed of these valuable hardy Cabbages, that they turn in during the autumn and are ready for use long before they are required. Too much attention has been given to the production of very early sorts which really are not wanted, because they turn in when Cauliflowers, early Brussels Sprouts, young Cabbages, Coleworts, &c., are plentiful, as well as late Runner Beans, Marrows, and other vegetables. It is not a matter of tradition, but of actual fact, that the tenderest eating of Savoy Cabbages is undoubtedly improved in flavour and texture by exposure to moderate frost. When, however, so advanced and frosted, then the hearts become strong or else decay. A variety that can be sown in June and will give small, compact heads like those of the Dwarf Green Curled or Early Ulm from November onwards is far more useful than varieties that heart in during September and October.—A. D.

## ROSE GARDEN.

### TEA-SCENTED ROSES.

PROFITING by the experience of last winter when so many plants were killed outright and others seriously injured by the frost, cultivators should be on their guard this year and see that material is close at hand to protect the plants as soon as there are signs of a severe frost. I do not think it desirable to use protecting material of any kind until it is really wanted, as the longer the growth is exposed the better condition will it be in to resist the cold when it does come. I find that in the west of England the only protection Tea Roses want is a cone of coal ashes heaped up the stem 6 inches to 9 inches high. Another good plan is to take some soil from between the plants and form a cone with it up the stem in the same way as is advised for the ashes. In ground that is likely to retain a deal of moisture in the winter, the removal of the earth from between the plants is of considerable importance, as it assists in draining away from the plants any excess of moisture. If I had done this fifteen years ago when I had a heavy and badly drained soil to deal with, I should have had a better opinion of the capacity of this class of Roses to endure frost. Most cultivators will be content if they can save a few inches of the main stem above ground, and by following the above advice they can do so in the majority of cases. According to my experience, the plants that suffer most from a severe winter are those from which the flowers are cut through the summer and autumn. In private places this would not, of course, occur to any serious extent, but growers who want all the blooms they can get and as late in the autumn as possible are not so favourably placed. It is these that should use efficient protection. It is quite reasonable to suppose that when the plants are cut about in this way they are considerably weakened, and therefore not in such good condition to go through a hard winter.

The condition of both the H.P.'s and Teas at the end of the summer just past was quite

conclusive that there are greater recuperative powers in the latter than in the former. I am alluding to plants that suffered the most from the cold of the last winter. The Teas in every case recovered more quickly than the strongest of the Hybrid Perpetuals. This has been so manifest all the season, that I regard the experience of much practical benefit for future operations.

I think we have still something to learn about the most suitable stock for weak-growing Tea Roses. The Manetti is too vigorous for such weak growers as Ma Capucine, Mme. Charles and Narcisse. Do what one will, the suckers are sure to appear, and then all hopes of obtaining a strong plant are lost. The trade, I think, should use a little more judgment in this matter and work the weak growers only on the seedling Brier. The greatest failure I ever saw through the influence of the stock on the plants was some twelve years or more ago at Canonteign House, Devon. At this place several hundred plants had been set out in specially prepared beds. At the end of the third year when I saw them, quite 60 per cent. of the plants were dead, all of which had been worked on the La Grifferaie stock. It is a consolation to know that this stock is not much used now.

Referring to the plate given in THE GARDEN for October 9 of the Tea Rose Narcisse, I do not think the drawing does the flower justice in point of colour. Perhaps one could hardly expect colour-printing to bring out the soft and delicate shading of this delightful Rose. You have not said a word too much in its praise as a garden Rose.

J. C. CLARKE.

## ORCHARD AND FRUIT GARDEN.

### PEAR DOYENNE DU COMICE.

THIS Pear is said to have been raised in the garden of Comice Horticole at Angers, and first fruited in 1849. In England it is by some considered the best Pear in cultivation, and should be included in every collection. Readers of THE GARDEN have frequently had its merits brought to their notice. It evidently delights in a fairly warm situation, and the tree that I have rarely fails to produce a good crop. It is growing against a wall and in a sheltered corner facing south. It scarcely ever yields any small fruit, or say weighing less than 10 ozs., while if the fruit is early and freely thinned out, the average weight is nearer 14 ozs. I have had individual fruits weighing 20 ozs. I have seen fine crops of large and more highly coloured fruit on more stunted trees also growing against a nearly south wall, and also good crops on cordons. In every case the fruit has been first-rate, the only rival to it being Marie Louise at its best. In many gardens pyramid and espalier-trained trees are to be found, and if these do not produce fruit equal in size and appearance to that on trees grown on walls no fault can be found with the quality. The tree is naturally of a stout and fruitful habit of growth, and I find the Quince stock does not greatly influence this. All things considered, the Quince is perhaps the best stock that can be chosen. The soil in which the tree is growing is a fairly strong clayey loam, or such as suits fruit trees for a long time at any rate. Some fruits that I exhibited in 1892 at a west of England Chrysanthemum show were considered by many people to be of foreign growth.

1.

**Synonyms in Apples.**—Very useful to intending purchasers must have been the lists given

in THE GARDEN lately of Apples sold under various names. There are, however, still many synonyms which I do not remember to have been mentioned. For instance, Pine-apple Russet is commonly known as Golden Reinette, the New Hawthornden as Graham's Giant, that popular Apple Pott's Seedling as Holland Pippin, Earl Moira as Spencer's Favourite, Sleeping Beauty, and Queen Caroline, Stirling Castle as King Noble, Fearn's Pippin as Clifton Nonsuch, Red Astrachan as Duke of Devon, Cox's Pomona as Red Ingestre, Court Pendu Plat as Woollaton Pippin, Blenheim Orange as Beauty of Hants and Prince of Wales, and the good old Rymer as Caldwell. Intending planters ought to be informed of these synonyms, as much disappointment is likely to follow.—J. C.

**Pears and birds.**—Where tits are numerous the majority of gardeners are always troubled in the same way as the two correspondents who

*Pear Doyenné du Comice.*

stated their experience in last week's GARDEN. Have they tried stout half-inch mesh netting? I have used it now for several years and find it answers the purpose admirably. No birds can get through this, nor, if it is propped by sticks far enough away from the wall, can they pick the fruit through the net. It is considerably more expensive at the outset, but, I think, cheapest in the end, as it also answers the purpose (double) for spring protection, and in all ordinary seasons will be found quite sufficient. For the benefit of those who have not already tried the experiment, I may note that "tapped" fruit can be preserved and ripened satisfactorily by the aid of plaster of Paris. Make the hole caused by the birds as dry as possible, and run in the plaster, smoothing down so that no air penetrates between the skin and the wound, and in nearly every case decay will be arrested and the fruit ripen off well. I remember saving a batch of Melons once in this way. They were just approaching the ripening

stage when a rat found its way into the pit and nibbled a lot of them. Premature decay would certainly have set in if I had not resorted to the plaster of Paris. As to the question of the birds, what a fastidious taste they possess. I have a Cornish Gilliflower Apple growing between an Adam's Pearmain and a King Pippin, and one would have thought the two latter, being much more attractive in appearance, would be tapped. No such thing; the birds ignore their existence and make straight for the Gilliflower, every fruit of which would be spoiled if I did not net the tree. There was, by the way, a remarkable absence of blackbirds and thrushes last summer. They must have succumbed in great numbers during the severe weather experienced early in the year.—E. B., *Claremont*.

**Apple Duck's-bill.**—I do not remember to have seen any reference to this cooking Apple in THE GARDEN. Probably it is but little known. When the tree under my charge first fruited, I, being ignorant of its name, sent a few fruits to the editor, who replied that it was Duck's-bill of Sussex. Since then I have seen it in the lists of several trade growers, and believe it is highly thought of in Sussex, the county from whence it takes its name. However, one thing is certain, viz., that for a long-keeping cooking Apple of splendid quality it will take a lot of beating. The fruit is of medium size, rather rough in the skin, and intensely red next the sun. If not quite such a heavy cropper as some standard sorts, its long-keeping qualities and general excellence when cooked entitle it to a place in every orchard. In March and April Duck's-bill is not to be despised in the dessert.—J. C.

### GRAFTING VINES.

CAN I with hopes of success graft Black Hamburgh on Foster's Seedling, Mrs. Pearson, and Madresfield Court? Also, can I graft Gros Colman and Black Alicante on Lady Downe's, Muscat of Alexandria and Syrian?—N. Y. Z.

\* \* Black Hamburgh Vines are frequently used as stocks for other varieties, and answer remarkably well too, but it is not often that this old favourite is grafted on or inarched on Foster's Seedling, Mrs. Pearson, or Madresfield Court. Doubtless "N. Y. Z." has good and sufficient reasons for wishing to change the character of the Vines of the three last named, but would have done well to state them. We graft or inarch comparatively weakly growers on to more robust varieties, thereby rendering them more easy of culture, while the more rank-growing, non-fruitful varieties can be made most productive by being established on stocks that have a restraining influence on their growth. Both the Black Hamburgh and Muscat of Alexandria are excellent stocks for either weakly-constituted varieties or shy-bearers. Madresfield Court also proves a good stock for strong growers, and I have known Foster's Seedling similarly utilised with good results. Mrs. Pearson is late in ripening and not a strong grower, but might yet be converted into a stock for Black Hamburgh. Gros Colman and Alicante would succeed well on Lady Downe's and Muscat of Alexandria, but I should say Syrian would not be a good stock for either of them, as it is a very strong grower. It is the usual practice to place one black variety upon another of the same colour, treating white Grapes similarly, but there is no real necessity for this arrangement. For instance, some of the best Gros Maroc I have ever tasted, or nearly the only berries of the variety that I could truthfully say were fairly good in quality, were cut from a rod inarched on to a Vine of Foster's Seedling. In this instance there was no appreciable difference in the size of bunch or berries on inarched rods and those on own-root Vines of Gros Maroc, but many years ago I remember taking note of the behaviour of rods of Black Prince inarched on to old Vines of common Sweetwater that had been largely planted in the vineries by mistake. Grand rods were formed and handsome bunches were expected. Instead

of this, neither the bunches nor the berries were any larger than those of the stock, all being decidedly small. That was what might be termed an unhappy marriage, and serves to act as a warning against grafting any but the most robust growers on to a weakly stock. Late, or comparatively late, varieties may be grafted on to early varieties, but if a rod or two of the latter is saved it will most probably be found that these will start a few days in advance of the late variety, and have all the best of them throughout in consequence. That was my experience with the Black Hamburgh as a stock for Muscat of Alexandria, and if "X. Y. Z." experiments so extensively as he seems inclined to do, he, too, may have some curious experiences to relate in future years. Bottle-grafting is the easiest and surest way of establishing one variety upon another, and this should be done after the stock has commenced active growth, the scions being dormant. If the latter are kept plunged in the open ground during the winter, this will retard them sufficiently.—W. I.

### THRIPS ON VINES.

How can I get rid of thrips, which has overrun an early vineery of Hamburgs and also Gros Colman and Black Alicante in a late vineery? The Lady Downe's in the same house and on the north side (the house is span-roofed) the thrips has not touched. Would it be of any use to take away during the winter the surface soil in the vineeries and replace it with fresh soil? With what should I paint the Vines? I have used soft soap, sulphur, tobacco-juice, lamp-black, and cow-manure.—X. Y. Z.

\* \* \* Of the two species of thrips the worst to contend with is the yellow one. In some gardens the Vines are very liable to be attacked by the latter, which, owing, I think, to the proximity of forest trees, has proved most injurious in spite of rather drastic remedial proceedings taken against it. In order to be effective, fumigation with tobacco paper must be strong, and if slightly over-heated or if the leaves happen to be damp, wholesale burning may take place. "X. Y. Z." will do well to once more try preventive measures. During the winter give the roofs and back walls of the houses a thorough cleansing, and then take the pruned rods in hand. Clear them of all loose bark, more especially about the joints or spurs, and then scrub them twice over with hot soapy water, every crevice or lurking place of the insect in any stage of growth being searched out. This will prove far more effective than thick vile mixtures such as "X. Y. Z." mentions. Too much value is often attached to this daubing of Vine rods. When the mixture used is too thick to be easily applied with a brush it is next to impossible to use it effectively, and in careless hands what is supposed to be a remedy very often proves quite the opposite, favouring the comfortable wintering of insect pests rather than otherwise. In addition to well scrubbing the rods "X. Y. Z." may dress them with a thinner concoction than formerly, substituting enough clayey water to slightly thicken it for the lamp-black and cow manure. After the rods are finally slung up, remove all rubbish and the surface soil in the vineery, quite baring the topmost roots, replacing with a rich compost, that is if it is an inside border and the Vines are in need of assistance. A dry atmosphere is very favourable to the spread of thrips, and in addition to keeping up the requisite amount of moisture in the air, keep a close look-out for any that may appear on the leaves, sponging with soapy water directly it is seen.—W. I.

**Showy Pears and Apples.**—Most of us have a weakness for showy fruits, and Pears are no exception. Unfortunately, the showy varieties take the eye and we must grow them. Beurré Clairgeau, one of the handsomest October Pears, if sent to market will command a good price, whereas the smaller and superior Louise Bonne of Jersey or Marie Louise will realise far lower prices. It

is interesting at our autumn shows to see how judges' tastes differ. Some say we must recognise size and dishes of Pittaston, Beurré Clairgeau, and even Grosse Calebasse and General Todtleben will be placed before Doyenné du Comice, Thompson's and Marie Louise. It requires strong-minded judges to pass over these large fruits and give the awards to flavour and good quality. I am pleased to note that the really good fruits are in a few instances given the premier awards. I think we have of late years paid far too much attention to mere size in fruit, and to a certain extent exhibitors now run in one groove, flavour, keeping qualities and any other good points being unnoticed in Apples and Pears. I also note many of the newer kinds of these fruits if large are much sought after by exhibitors. Many new Apples have been raised during the last quarter of a century, but how few of these are equal in quality to the older kinds. I admit size in most cases is the only gain, this being at the loss of quality. I recently noticed in these pages a plea for classes of fruits at large exhibitions of those kinds noted for quality, size being of secondary importance. I gladly note this plea for quality, and would go further, and add we may also consider keeping qualities and the crop also, as many of the large showy fruits are indifferent croppers and poor keepers. Some of the newer Apples and Pears cannot be termed second-rate. Large Apples and Pears are very misleading.—W. S. M.

**Damsons.**—I was much interested in the article by "W. G. C." (p. 357) on Damsons, and I should like to impress on anyone who is going in for their culture to bear in mind the fact that, although they certainly do grow and bear fruit in almost any kind of soil or situation, there is a vast deal of difference in the crops borne by trees planted on good soil and those on stony, thin soils. The prevalent idea that a hedgerow or any out-of-the-way corner is good enough for Damsons is, to say the least, most unfortunate. I had this fact very forcibly impressed on me during the past summer. I planted a good many trees, mostly of the Crittenden or Cluster Damson, during the past twelve years, and they are now fine trees, for having pruned them after the Kentish style, stopping all the strong shoots, they have dense heads of short fruitful spurs, and the tiny shoots are as thickly set with fruit as bunches of Grapes. During the severe drought in June and early part of July the trees suffered considerably where planted on light stony ground, the foliage dropping off by reason of red spider attacks, while a good deal of the fruit dropped as well. On deeper and richer soil the trees finished a splendid crop. Of course, very much could be done by mulching, watering, spraying the trees, &c., to check red spider, but there is nothing like planting on good soil and treating liberally afterwards. Large fruits sold freely, while the small ones were a drug on the market.—J. GROOM, *Gosport.*

### NOTES ON THE HEREFORD FRUIT SHOW.

At the above show, held November 5 and 6, there were several very interesting features not usually present at many of our exhibitions. One of the most striking was a collection of cider Apples and cider sent by the French Pomological Society. Each dish consisted of ten Apples, selected from six districts in France, viz., Normandy, Picardy, Morbihan, Côtes du Nord, Loire Inférieure, and Ile et Vilaine, sixty plates or ten dishes from each. For comparison, Mr. J. Watkins, Pomona Nurseries, Hereford, staged thirty-eight dishes and nine baskets of Herefordshire cider fruit, which far surpassed the French exhibits in size of fruit, colour, and cleanliness. To make his display more interesting and instructive, Mr. Watkins had labelled each variety in a manner similar to the French fruit, stating its qualities as a cropper, habit of growth, its bloom, fruit, juice density, flavour, sugar, and tannin. It appeared from the lecture delivered by Mr.

Radcliffe Cooke, M.P., on cider-making in France and the system of exhibiting, that all exhibitors are obliged to give full instructions as to the variety, form of growth, situation, aspect, soil, &c. In this way their shows are infinitely more practical and of greater national service than our own, and I feel convinced that if we adopted similar plans at our hardy fruit exhibitions there would be fewer useless sorts grown and a better class of fruit generally cultivated in this country. It is to be hoped that an important society like that of Herefordshire will see their way to adopt this improved system in the future. Several thousand dishes are annually staged at their November show, and if all these varieties were labelled as described above, there is no question that the society would give a grand object lesson and confer a lasting benefit on the county by indicating to intending planters what to plant and what to avoid. Take, for instance, Belle Dubois or Gloria Mundi Apple, which was staged in fine condition; very few would plant it if the variety was described as a strong grower, prone to canker, shy bearer, seldom producing a good crop, fruit often of ugly shape, and very uneven in size. There are many other Apples and Pears that are staged in splendid form at our great shows that would seldom be planted if their true character was thus defined, and it must be patent to all practical men that some such measures are necessary to make our fruit exhibitions what they ought to be.

Pears in the collections were not so well represented as on former occasions at Hereford, but the single dish classes were first-rate. The Doyenné du Comice Pears which secured the premier award for Mr. J. W. Bulmer were magnificent, and the same applies to the Marie Louise staged by Dr. T. A. Chapman, who was an easy first. In the any variety class of Pears for flavour, Lady Emily Foley, Stoke Edith, secured first place with a delicious dish of Thompson's. In this class there was a great difference in the same varieties, only two good dishes of Thompson's appearing; the flavour of the others was poor. Marie Louise could be described as fair, Doyenné du Comice surpassing it, but not equal to the first prize Thompson's. Cox's Orange Pippin obtained first place as the best-flavoured Apple, and the dish of the same variety in the first prize collection of thirty dishes of Apples from Clawston Court gained the award for the best dish of dessert Apples in the show. A prize was offered by Mr. J. Wilson, Hereford, for a more tasteful arrangement of cut blooms of Chrysanthemums. The stand taking first prize was a decided improvement on anything else seen at Hereford. The blooms were well up above the stands, which were faced with nice green Moss, on this sprays of Maiden-hair Fern had been fixed, on which the blooms seemed to sit. At the close of the second day the Fern appeared as fresh as if only just picked, and, judging from the unstinted praise and admiration bestowed on this exhibit by ladies and others, this style of showing cut blooms is worthy of imitation. Several competitors in this class had placed coloured foliage on the stands as a groundwork, but the effect was by no means pleasing or in good taste, as the colour of the blooms and the foliage did not harmonise at all well.

W. R. H.

### NOTES FROM ALMONDSBURY.

**IPOMEA R. CERULEA** has been blooming freely here. Some forms are pure white, but the common type is a wonderfully fine blue. Why does this Ipomoea develop rather blunt thorns on its leaves and stems? I have never noticed them before. I once saw a deep-coloured Castor-oil Plant about 8 feet high outside an iron house in Kimberley covered with this Ipomoea; the effect was very fine. Lately I had some roots of Ipomoea pandurata dug up. After digging down 3 feet my gardener broke off the root, a solid mass about 6 pounds weight like an enormous potato. I wonder how much was left in the ground. This species blooms well here. I bloomed single Cactus Dahlias this year in five

months from seed, and have now quantities of Cyclamen in bloom from seed sown in February. The Marguerite Carnation is an instance of the same kind. My own plants have had no very great care bestowed on them. There are some plants I should like to hurry up a bit. *Eremurus robustus*, a five-year-old when procured, I have cared for for three years, but I think it doubtful if I shall bloom it in 1896, and when it has flowered it will probably disappear. *Iris Kaempferi*, auction bought dried clumps, bloomed well with me this year. I have never done anything with them before. The secret is rich soil and putting them near a pump, whence give them a daily soaking. For a quaint, tall and graceful winter blooming plant let me recommend *Antholyza bicolor* in a pot. I know nothing quite like it. I accidentally dried mine

#### MUSA ENSETE IN CORNWALL.

THE Abyssinian Bananas here shown are *Musa Ensete*. The one at the extreme right is 10 feet high. The seed was sown in February, 1894, and the seedling was planted out in the open in June of the same year. The plant was taken up and put into a box at the end of October, and put out again last June. The one on the right of the figure was raised from seed in June, 1894, and planted out this last June. The large one on the left was 12 feet high last October, when I put a wooden shed over it. All the old leaves died in March and those shown are this year's growth. A small one at the extreme left survived two winters with only mat pro-

and north winds being apt to disfigure the foliage and lower its blooming capacity. It also requires a well-drained soil, thriving better in light soils than in those of a heavy character. Where soil and situation are favourable this *Clethra* should find a place.—J. C. B.

#### CHRYSANTHEMUMS.

##### SPOILING THE CHRYSANTHEMUM.

SOME years ago I wrote a note on this subject in THE GARDEN animadverting on two points in connection with our great autumn flower—the tasteless and hideous way in which it was

*Musa Ensete* in the garden of Mr. Howard Fox at Roschill, Falmouth.

off in the summer; now they bloom at the time they would naturally in their own country. Would not more plants from Africa's sunny climes prefer to bloom at the time natural to them if they were encouraged to do so? The new *Physalis Franchetti* is very much admired here; the colour is wonderful. I am sowing seed to-day. *Erythrina crista-galli* as well as *E. Kaffreana* are among my failures; the latter has severe thorns on both sides of its leaves. I hear it blooms freely in Grahamstown gardens, whence indeed my seed came. There it has a good deal of rain in winter and a very hot sun in summer. The Water Lily garden pictures are very charming. My brother, Frank Miles, took a great deal of trouble with these. It is delightful that another has succeeded so well with them.

C. O. MILES.

tection, but the roots were mostly killed and it had to make new ones; hence the diminished size. The shrub immediately behind the figure is *Desfontainea spinosa* in full flower. The *Acacia* in the background is *A. lophantha*, behind this *Cordyline indivisa*. The shrub to the left of the big Banana is *Carpenteria californica*, which flowers annually. The bed in which the big Banana is has an edging of *Iresine* from 1 foot to 2 feet high.

HOWARD FOX,  
Roschill, Falmouth.

*Clethra alnifolia*.—There is something very attractive in a well-developed specimen of this flowering shrub. It is unfortunately somewhat tender and requires a sheltered situation, cold east

shown and the way in which florists were destroying the whole natural grace and beauty of the *Chrysanthemum*. Since that time an immense reform has taken place in the way in which all flowers are shown at our horticultural exhibitions, and taste and individual fancy are fast removing the old soul-deadening monotony which was dictated by the want of taste of the old florists, whose ideas of beauty were founded on the compass and the cut Turnip. In the *Chrysanthemum*, amateurs have had sufficient courage also to rebel against their gardeners and to discard that hideous Cauliflower-like abortion, the incurved variety, and to put an end to trained specimens. Little progress has been made, however, in giving us fairly good

single varieties, which to my mind form the most expressive development of the Chrysanthemum. For instance, so far as I know, there are no singles offered which are early enough for the open air, though they are far more capable of surviving damp and early frosts than heavy double flowers crowded with petals, and which can only really come to perfection in quite dry and fairly warm weather. So far as indoor Chrysanthemums go, it is true that the incurved varieties are being driven out, but a heavy price is being paid for this victory. The elegant wildness and orderly confusion of the Japanese sorts are being trimmed away into as close an imitation of the lamented incurved kinds as our florists dare to venture upon. We are presented with flat monstrosities with thick, tangled centres and a fringe of irregular petals. The Cauliflower or cricket ball ideal of the florist is now succeeded by as close an imitation as possible of the domestic mop, stick and all. It is true that the stick is being shortened, simply because ordinary humanity is not tall enough to live up to the floral level of the show Chrysanthemum. We already have flowers of this sort as big as the top of a hat, or even as a small soup plate. Within a few years, if we progress in this fashion, the mop ideal will be reached, and we shall have exact copies of that familiar implement in size as well as in general appearance. Surely this is not progress, but retrogression. As time goes on, people of taste in floral matters are more and more considering the Lilies of the field, and finding how true it is that all the glories of Solomon cannot vie with them. They are realising that every flower has a natural character and expression, and that to pervert these is to bring about the survival of the unfittest, not only from a scientific, but from an artistic point of view. Hence the revival of the taste for natural hardy flowers, and the preference for the humble flowers of the Alps and of our own and other fields, hedges, and woods, instead of for the pedantic and ignorant fancies and taste of the "florist" of thirty years ago. To all this general progress the Chrysanthemum is an exception. It is retrograding and spoiling under the perverted taste of our great growers and fanciers. For all decorative purposes the outdoor sorts, poor as they are, are infinitely preferable to the newest prize varieties, notwithstanding all their gold, silver, or bronze medals. We have improved the way of showing Chrysanthemums, but that is useless if the flower itself is to become an ugly monstrosity.

J. I. R.

#### FADED CHRYSANTHEMUMS.

WHEN blooms that have long drooping florets are staged from a week to ten days after they were at their best, then every day, especially if the weather be damp, tells upon them adversely, the lower petals turning brown and wearing a dirty, bedraggled appearance. The presenting of such blooms at a show is a grave mistake. If judges, less dazzled by mere size and bulk, would resolve to ignore these large stale blooms and to favourably regard only those even if somewhat smaller, yet quite fresh, we should soon cause the entire disappearance of these stale blooms, not a few of which have already done duty at shows several days previously. To require size, depth and solidity in Japanese flowers early in November is all very well, but later these requirements should be made secondary to freshness and brightness, with an entire absence of stale or dirty petals. Such blooms as these would be as creditable to the grower in the middle of November as would blooms equally fresh and one-third larger and fuller when the month opens. Looking over the recent show at Kingston on the second day, I could but notice in brighter light how favourably

the incurved Japanese flowers compared with those of the loose-petalled section. These have no bedraggled aspect, and, because of their solidity and substance of petal, seem to keep fresh so much longer. It seems as if for late showing it would be wise to grow these solid incurved varieties more largely. Their demerit is that they are stiff and formal in appearance compared with the more tasselled flowers. If, however, they are less susceptible to damping and keep fresher so much longer, then their merits in these respects to a large extent counterbalance their demerits. Blooms of this description being, as a rule, not so large as are the flowers of the tasselled section, do not harmonise with them in stands, but they would very well with second-sized very fresh flowers, especially of such varieties as Colonel Chase, Commandant Blusset, William Seward, Golden Gate, a lovely variety, and others of that solid reflexed type. Apart even from the difference in freshness tasselled and incurved Japanese flowers present later, the two forms need division, and a regular section of incurved Japanese should be formed. Very fine and fresh at Kingston of the latter were Robert Owen, Lord Brooke, Louise, Viscountess Hamledon, Mme. Rozain, Mme. Alf. Chatin, Mr. Denne, R. C. Kingston, deep red, Silver King, Beauty of Castlewood, Mrs. Harman-Payne when of incurved form, and the quaint Good Gracious, which belongs almost to the type. The American Philadelphia incurved Japanese was at Kingston very poor. Probably we shall see little of it in future years. However, the list given can be largely added to, and those who grow the section for late purposes will find there is great gain. That superb variety Robert Owen is a good keeper, for a good bloom of it last year was shown two weeks in succession. However, I do not advocate the holding over of flowers in that way, far from it, but the fact stated serves to show how well the incurved varieties keep. One advantage resulting from the holding of shows over so long a period as four weeks is that whilst some encourage the production of early flowers, others favour late ones, and thus the blooming season is prolonged.

A. D.

#### CHRYSANTHEMUMS AS ANNUALS.

WHEN we look back upon the last decade of Chrysanthemum-growing it is quite easy to discern the great strides that have been made, more particularly with respect to English-raised seedlings. Indeed, the advances seem so great and the seedlings obtained so meritorious, that our friends across the seas (French as well as American) will soon find formidable rivals among the specialists in England. Less than ten years ago Mr. Robert Owen, of Maidenhead, was undecided as to the best way of securing seed from home-grown plants. To-day his name is almost a household word as a raiser of some of the finest English seedlings. The whole thing is so interesting, especially so to amateurs whose living is not dependent on the results of their labour, that anyone having a small house at disposal may grow and prove a few seedlings each year. The seedlings are so varied and very often so different from what may have been expected, that novelties are sure to result. For two or three years past I have raised a few seedlings from my own seed, and the results are so encouraging, that I am tempted to detail my experience for the benefit of those having more spare time at their disposal. I have not the slightest idea upon what lines our English specialists save seed, or what they consider the surest way to secure a plentiful supply of pollen. My own notion of the matter is that two-year-old plants may invariably be relied upon for securing pollen in plenty, and not only this, but flowers also of a kind that are more certain to ripen seed. The plants intended for seed-bearing must be set apart from those which are

grown for flower-producing, and should on no account be highly fed. Indeed, two years ago I harvested a nice bit of seed in December from cuttings inserted in the June previous, but this is an exception to the general experience. By confining the plants to medium-sized pots and a poor soil, flowers thin and poor in character will result, and these are much the best even in the first year. Then the same plants may be grown another year also, and the thin, wiry wood that follows will be found first-rate for the purpose. What I have done so far has been with white and yellow kinds, and with a view to get a more generally dwarf habit. We have now some good material to work upon of dwarf habit and bearing fine flowers, so that it should be easy to keep the stature of all future kinds within reasonable limits. Where the pollen is not required, I pull out all the disc florets and anthers; this I find causes the outer florets to come more to the centre.

The florets are cut away with a pair of scissors. Where this is done while the flower is comparatively young, what is left of the florets often expands, and thus the essential organs are distinctly visible. By the aid of a lens these latter may be watched from day to day, and when ready to receive the pollen may be duly fertilised and noted accordingly. There may be other ways equally successful for securing flowers and pollen, but the above is my own experience and which so far has proved successful in seed-producing.

By growing the seedlings in pots the plants may be flowered the same year; in fact, I have some plants now going out of bloom from seed sown on January 10, 1895. The first seedling appeared eight days after the seed was sown, and the plant flowered early in October, at about 3 feet high, the growth very compact, the flowers chestnut-bronze. This resulted from crossing two yellow kinds, Mrs. Hawkins as seed parent and Admiral Symonds as pollen parent. Two of my unflowered seedlings of 1894 have produced pure white flowers, in one of the exceeding purity of Elaine. These being too late to flower last year, have been simply grown on for proving, carrying four or five stems each; notwithstanding, the flowers are very double. These will be duly tried another year. With the two-year-old plant system, however, many seeds can be ripened for sowing early in January, and the seedlings be flowered the same year, treating them as annuals in fact. Where the hybridising of very late kinds is carried on the seed will hardly be ripe in time, unless the lateral buds from plants that have produced large blooms are used. These laterals often flower from February to April, and where pollen can be secured at the same time the seed will have a good chance of maturing during the summer. To get these flowers, the plants blooming in the previous autumn should be saved with all the stem intact.

E. J.

**Black-fly on Chrysanthemums.**—How can I get rid of black-fly on Chrysanthemums which have been troublesome during the whole summer? The plants were in every respect, so far as culture is concerned, properly treated.—N. Y. Z.

\* \* Many growers have been troubled with the small black aphid on their plants, but if they would persevere with the syringe, using nothing but clear cold water, they would find this a simple and most effective remedy. Should this not prove quite equal to getting rid of the tiny pests, then tobacco powder ought to be well puffed into the points of the shoots overnight and be syringed off next morning. If by chance a few aphides are housed with the plants, follow them up with the powder and syringe, not delaying this till the in-

sects are established in the blooms, as then there is no getting rid of them without removing the blooms as well.—I.

**Exhibiting Chrysanthemums.**—For a long time past much has been written advocating an improvement on the bare, broad style of exhibiting blooms. I am pleased to observe that the N.C.S. and other societies are encouraging displays of blooms in vases, but as yet the competitions have principally been confined to the Japanese section. Of all the classes which are improved by this manner of exhibiting, none can compare with the singles. At the late exhibition of the N.C.S. I was grieved to see boards were still used. Surely no objection can be raised against vases for exhibiting singles. Why do not the various societies have classes for singles exhibited in sprays, say six sprays of each variety? Again, a standard excellence should be set up. The inference to be drawn from the awards made at the N.C. Society's show is that size is everything. Many hold the opinion that form, brightness, or clearness of colour, combined with medium-sized blooms, should be preferred to the large, coarse flowers which are sometimes honoured by the chief prizes. In single Dahlias, size is a secondary consideration.—S. C.

#### CHRYSANTHEMUMS AT MAIDENHEAD.

The Floral Nursery, Castlehill, Maidenhead, where Mr. R. Owen has been established so long, is situated in a spot that must be peculiarly favourable for the culture of the Chrysanthemum when we consider the close proximity to the great metropolis of some growers who achieve great results with this popular autumn flower. For some years past Mr. Owen has materially contributed to enlarge the list of sterling novelties both from his own seed and by selections from the seedlings of American and Continental growers. This year again his collection is a comprehensive one, and comprises new varieties under trial from Africa, France, Italy, America and other places. A large number are therefore unnamed and cannot be individually referred to, but we were struck on the occasion of a recent visit with a French friend at the wealth of colour, especially in bronze and crimson shades, that these new seedlings display.

The *dite* of the collection finds a home in the large greenhouse, and some finely-developed blooms were on view there a week or ten days ago. Most of the flowers belonged of course to the Japanese section, although new Anemone-flowered and incurved varieties claimed a place. As many of the varieties of the older known sorts have already been fully dealt with in THE GARDEN earlier in the season, there will be no need in this article to do more than briefly refer to such as were in good form at Maidenhead when we called. Of these, Col. Chase, Pallanza, Junon, Beauty of Teignmouth, and Mme. Paul Lacroix were perhaps the chief.

In new incurved, the yellow *Globe d'Or* and Charles H. Curtis take the lead. Robert Petfield, of the same section, and its golden bronze sport *George Haigh*, which will no doubt be well received when put into commerce, are both good forms. Mrs. R. C. Kingston, introduced last season from America, is a delicate silvery pink, and in the same class Owen's *Crimson*, the name being sufficiently descriptive; John Fulford, golden chestnut; *Rose Owen*, pale rose, very round in outline; and a golden buff incurved, *Ada Fulford*, should interest all lovers of this somewhat ancient, but still highly esteemed type.

More varied in size, form and colour is that protean favourite, the Japanese. There are several raised in the Australian colonies—*Lady Gormans-town*, white, *Pride of Launceston*, and *James Lynch*, to wit. The Italian novelties are small in size, but very distinct in colour; they are not, however, judging by past experience, likely to obtain a very high position with English cultivators, and their style of nomenclature sadly needs some revision. *Pride of Maidenhead* is a large Japanese raised by Mr. Owen; it has long florets and is pure white with a pale primrose centre. Gen. Roberts,

with medium sized florets, colour reddish crimson and golden reverse, is striking and effective. *J. Bidenscope*, large and massive, having twisted florets, colour deep rosy amaranth, reverse silvery, also attracts attention, but the blooms of *M. Aug. Lacvievier*, deep golden yellow suffused salmon-rose, are the finest we have seen of that variety this season. Major Bonaffon, an intermediate form of Japanese incurved received from America, is very pure yellow. *Mme. Rozain*, a large incurved Japanese, colour silvery rose, was spoken of by us highly last year, and maintains the high opinion then formed of it. In *Lady Ridgway* there is a richness of colour, salmon-buff, tinted gold, not too often found even among Japanese. *Pride of Launceston* is a colonial novelty and worthy of a note, being velvety violet-amaranth. *Graphic*, white, suffused purple, is large and useful to exhibitors, and the same may be said of *Mme. Paul Lacroix*, pale yellow.

*M. Calvat's* seedlings are represented by *Directeur Tisserand*, yellow and crimson, a novelty only sent out this spring by H. Jacotot fils, deep velvety-crimson with reverse of golden bronze, and *Reine d'Angleterre*, a very large Japanese with flat florets rosy-purple in colour. From the same source comes *M. J. Ginot*, a bright-coloured novelty of this year's introduction.

A few hairy-petalled novelties are to be found in the Maidenhead collection, notably *Vaucanson*, figured in THE GARDEN on January 26 last; *Esau*, well deserving of its name, having very hairy long tubular florets, colour rosy-amaranth; *Glasnevin*, deep purple-amaranth, and *Prima Donna*, chestnut-bronze.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Hairy varieties.**—Going the round of the trade displays, only a few of these have been met with this season. *Hairy Wonder* (bronze), *Enfant des deux Mondes* (white), *Mrs. Alpheus Hardy* (white), *Mrs. Dr. Ward* (golden yellow and bronze), *King of the Hirsutes* (yellow) were among the most attractive.—CHRYSANTH.

**Chrysanthemum Son Altesse Sidi-Taieb Bey.**—Although a rather lengthy name, this variety is a pretty little October-flowering Japanese Chrysanthemum. When freely grown in the open border it will be very useful for cutting. The colour is pale lilac-pink. It is of French origin, and although not widely known, has been in cultivation for several seasons here.

**Chrysanthemum Miss Louise D. Black.**—This is one of the American novelties for the year and a striking flower. The colour is rich orange-gold that shows well under artificial light. This is a great point with yellows, as so many of them are wanting in colour at night. The flowers of this kind are solid and compact and of large size. The plant is of good habit, between 4 feet and 5 feet high.

#### OCTOBER IN SOUTH DEVON.

The rainfall during the past month has amounted to 4.05 inches, to which must, however, be added the 0.27 of an inch which fell on the early morning of the 1st, and which, therefore, had already appeared in September's record. The rainfall of October, 1894, amounted to 7.76 inches, and the average for the last nineteen years to 4.34 inches. There have been twenty-one wet days in October, 1895, against seventeen in October, 1894. The heaviest fall in the twenty-four hours occurred on the 8th, when 0.88 of an inch was registered. During the ten months of 1895 20.74 inches of rain have fallen, against an average of 27.64 and 33.31 inches for the corresponding period of 1894. The mean temperature for the month has been 49.6°, that of October, 1894, having been 52.3°, and the average temperature 51.4°. The lowest reading recorded on the grass at the observatory was 25.7° on the 24th, but in a low-lying valley where there is water in quantity 10° were registered. From the 24th the thermometer on the grass fell below the freezing point on seven days. The sun has shone for 100 hrs. 50 min. during the month, thus beating the record of October, 1894—90 hrs. 45 min.—by over 10 hours, but being far below the average, which is 116 hours. The wind,

though considerably more active than in September, in which singularly still month only 3175 miles of lateral movement were recorded, was far less boisterous than in the months of July and August—a rare case for the equinoctial month of October—the amount registered being 6443 miles, almost precisely similar to the record for October, 1894, while the lateral movement in the months of July and August exceeded 7000 miles in each case. The greatest daily velocity was 531 miles on the 3rd, the greatest in an hour occurring between 12 noon and 1 p.m. on the same date, when the rate observed was 41 miles. The direction of the wind has been southerly to westerly for twenty-one days, and north to east for the remaining ten.

Although October is not a month of varied display in the garden, many of the September flowers held out bravely until cut down by the frost of the 24th. The *Begonias* lengthened their already long season of bloom with as brilliant effects as in the preceding months. The last of the perennial *Sunflowers*, *Pyrethrum uliginosum*, *Rudbeckia Newmanni* and the later *Starworts*, of which *Aster grandiflorus* with its large golden-eyed purple flowers is one of the most effective, vied with the *Dahlias* in brightening the herbaceous borders. Small clumps of *Dianthus Napoleon III.* gave patches of deep crimson here and there, and the blooms of *Stokesia cyanea*, some plants of which perished during the last severe winter, added a tint of deep violet even darker in shade than that of *Aster grandiflorus*. *Doronicum plantagineum* Harpur Crewe produced its great golden stars in almost spring-like profusion, and each morning a few fugitive blossoms of *Papaver pilosum* were to be seen fluttering frail petals on the high bank. The flowers of the yellow *Paris Daisies*, though scarcer than in September, were charming as ever, and near the sheltered Lily bed the *Acanthus* threw up tall spires of bloom, while *Erythrina crista-galli* and the scarlet climbing *Tropaeolum* continued to provide a but little diminished show of colour. Perhaps the most decorative plant of the month was to be found in the *Winter Cherry* (*Physalis Alkekengi*), which grows strongly here, making shoots quite 3 feet long studded with brilliant orange-red calyces. Arranged with autumn foliage and yellow Chrysanthemums, these sprays have a charming effect. *Solanum jasminoides*, a valuable climber in the south-west, has been everywhere smothered in white flower clusters. Even plants that were badly cut last winter are making a good show of bloom, and I have heard of no instance where it has been killed outright in this neighbourhood. *Magnolia grandiflora* has afforded a dozen or more flowers, but smaller than their predecessors, and the white *Macartney Rose* day by day, until the advent of the frost, opened its chaste single blossoms, which have been produced with intermission since the last week of July. Self-sown seedlings of the Mexican Daisy (*Erigeron mucronatus*) have flowered well, but the old plants succumbed to the long-continued frost of the commencement of the year. This pretty little plant seeds very freely in places, and the other day, on going over a friend's garden, I found a numerous colony flowering in the chinks of a wall, whither the seed had been blown from the parent clump, which was situated many yards distant. A striking feature in the garden during the early part of the month was the abundance of the little brown moth (*Gamma digamma*), which I never remember to have observed in such quantity, and which in the still evenings hovered over the tall heads of the *Michaelmas Daisies* in such countless throngs as to almost eclipse the blossoms, giving the impression of an ever-shifting kaleidoscope in which sometimes the lilac of the flowers, sometimes the umbr of the moths' wings, predominated. Talking of *Asters* and insects, the dwarf *A. dumosus* seems the most appreciated by the bee tribe, on a sunny day scarcely a bloom being untenanted by either a yellow-banded humble bee or its brown sister of the hive.

The extreme heat of September has evidently had an unusual effect on vegetation, as during

the first three weeks of October Primroses could be gathered from the hedgerows. Laburnum was in bloom, as was *Cytisus racemosus* planted out in a sheltered position, while ripe Strawberries and Raspberries could be picked in the kitchen garden, where Apple trees were bearing at the same time fruits, some fully ripe, others of the size of Walnuts, as well as rosettes of fully-expanded blossoms at the ends of the shoots.

The frost, which has now left the garden desolate, arrived much earlier than is usual in this locality, Christmas being often reached before more than 2° or 3° are registered on the grass. A limit has now been practically set to the outdoor flowers of the year, and, with the exception of the Christmas Roses, of which the first flowers from *H. altifolius* were cut on the 6th of the month, *Iris stylosa* (the Winter Flag), *Schizostylis coccinea*, and stray blossoms from Safrano or other Tea Roses on sheltered walls, there will be little to mark till the coming of the first Snowdrop. S. W. F.

### TREATMENT OF LAWNS.

I SHOULD be obliged by your informing me of the proper manure for lawn and cricket ground. They are already in pretty good condition, but I want to improve them. The soil is light.—J. G. C.

\*\*\* A really good and well-levell'd lawn or grass plot, to use an old English name, is what is wanted near every country house as well as in mere public places. Such a flat and even lawn may be used for such games as cricket, croquet, and tennis. In all cases evenness of texture and short-shorn grass are essential. A well-made and neatly-kept grass plot is a constant source of pleasure in many ways, and during hot summer weather it becomes, as someone once termed it, "a mental salad"—so grateful is its velvety texture and cool hue to eyes full of heat and bright colour. One may now and then see lovely breadths of smooth, clean, and well-kept lawns near country or even near town houses, but with one or two rare exceptions the finest lawns I have ever seen are in the grounds attached to the colleges at Oxford and Cambridge. Perhaps in no other town or city in the world can such rich and perfect carpets of grass be seen; and there is a story of a rich American visitor who, after tipping one of the college gardeners handsomely, ventured to ask him what was the secret of such perfection. The man looked at his visitor a moment and then answered, "Well, you see, Sir, this is how it be. There is no secret at all about these grass plots, but they've been rolled and mown for nearly a thousand years." There is of course somewhat more than a grain of truth in the story, for constant rolling after rain and constant mowing (especially with a scythe) exert a wonderful effect on turf, as is generally well known. But when grass is mown and carried away for years and no return made, even the best of lawns deteriorate; and so it naturally follows that some return in the shape of manurial top-dressings at least once every year must be given to the soil in which the grass is expected to flourish. If this top encouragement is not afforded the grass becomes thin and weak, and ill weeds, such as Daisies, Plantain, Dandelion, Hypochaeris, or in damp and shaded places even Docks, Groundsel, and Nettles will usurp the vacant spaces. Constant mowing is efficient, because grass bears cutting far better than do the weeds, and the same is in a measure true of periodical rolling after showers, but the royal road to fresh, green and clean lawns is due in a great measure to the well-directed application of manure to the grass. In a word, good feeding and quickly repeated mowings and rolling are at the bottom of good keeping so far as lawns are concerned.

From February to April is the best time for the application of top-dressings, but they may be applied at all seasons if finely sifted materials be used on the approach of rain. When I was admiring the lawn in St. John's Gardens at Oxford some years ago the gardener there told me that a mixture of sulphate of ammonia, finely sifted earth, and burnt refuse or wood ashes was used there, and he showed me patches of Daisies that had been scorched away by the application of the sulphate during hot and dry weather. Having at that time become responsible for some acres of rough and weedy lawns, I made many experiments with manures, and after repeated trials I find the following mixture gives the best results on a light and dry limestone soil: Finely sifted or screened earth, 5 parts; sulphate of ammonia, 1 part; kainit or wood ashes, 1 part; bones reduced by acid, 2 parts; soot and fine coal ashes, 1 part. Supposing each part to equal 1 cwt., we get here 10 cwt. of a mixture that forms a good, active, and lasting manure for 5 acres of lawn. In some cases I used nitrate of soda instead of the sulphate, as it is cheaper, but found that it did not act on the soil so efficiently as did the best sulphate from the gasworks at about 12s. per cwt., the nitrate costing about 9s. per cwt. I have tried farmyard manure, cow manure, bone meal, basic slag, fish and soot manure, but none of them alone in any way equals the permanent effects of the mixture I have given. Another excellent and lasting mixture is made by mixing thoroughly in a dry place 2 cwt. of bone superphosphate and 1 cwt. of kainit along with 5 parts of sifted earth. This should be applied in spring, say about March, and in April or May it can be followed by sowing nitrate of soda at the rate of 1 cwt. to the acre. Bear in mind that two top-dressings of 1 cwt. to the acre at an interval of a month or six weeks apart are far more advantageous than one dressing of 2 cwt. to the acre. I have used both the manurial mixtures in above proportions to flower beds and shrub borders with the best results, and they have been especially serviceable used rather more freely in renovating the grass where it is apt to become thin and sparse immediately beneath or near spreading trees.

There are many fine lawns in England. Indeed, the one thing American and Continental visitors to our shores first notice is the perfect green sward around our country houses. There is a very perfect bit of lawn at Hawth Castle, fresh, soft, dense, and velvety green without a weed in it, this perfection being due to the personal supervision of the Earl of Howth himself, who thinks good lawns and fine old trees the perfection of good gardening. As Hawth Castle grounds are open during the early summer months, the visitors who go there to see the stately old Beech hedges and Grass alleys and the great masses of Rosemary, Lavender and Thyme, and the superb standard Gloire de Dijon Roses should not forget to ask permission to see the "velvet lawn" which lies in front of the house, where visitors, as a rule, are not permitted to wander alone. I am not aware that any chemical manures have been applied to the Hawth lawns, but they are copiously top-dressed every winter and spring with sea sand and finely screened earth, and are mown every few days during showery weather. The results thus obtained are most satisfactory.

Wherever artificial or chemical manures are not readily obtainable, an excellent home-made mixture may be made up of old Mushroom house or hotbed manure, soot, wood ashes, or other burnt refuse, and even dust-like coal

slack and coal ashes may be added with advantage to damp and mossy lawns. All should be well turned over and mixed together, and finally when dry run through a half-inch screen or sieve and applied at the rate of ten or twelve tons to the acre. Above everything do not starve the Grass, and if possible during summer it should be mown and rolled every five days.—F. W. BURBIDGE.

### BOOKS.

#### IN VERONICA'S GARDEN.\*

HERE we have another charming volume by the author of "The Garden that I Love," and here also we renew acquaintance with Veronica, Lamia, and the Poet, and are again dazzled and entertained with the polished wit of their discourse. Veronica's garden is a rich jungle of Grass in spring, out of which rise shapely Pine and Fir—the Scotch, the Silver, the Nordmann, the Lawson, all fresh-tipped with golden green, and dotted among them shines the bright growth of young Beeches. To the right a scarlet Thorn just opening its brilliant flowers; to the left a Quince, "the most brilliant of all flowering shrubs, every long green curving branch starred with large single delicate pink and white blossoms—a fountain of bloom"; a group of golden Elder and a group of Spanish Broom "marvel of whiteness." Sugar Maple and Liquidambar reserve their beauty for the autumn, but late Tulips peep through the tangled Grass. Through the curving branches of a patriarchal Oak are seen irregularly dotted groups of flowers, wild and cultivated, wild Hyacinths, blue, pink, and white, Poet's Narcissus, little colonies of Columbine, and the green spears of Daffodil leaves. In the formal beds the Tulips have disappeared, but the Forget-me-nots are there still in the zenith of their amethystine bloom, and in the mixed beds and borders Oriental Poppies, yellow Dahlias, dark red Valerian, and snow-white Columbine. The eye wanders over Lilac, Laburnum and Guelder Rose, golden Berberis and silvery Japanese Maples, Rhododendrons, Azaleas, and the first rich red shoots of Tea Roses sprouting daintily above purple Violas—a perfect vision of garden beauty. Of birds they have enough and to spare—nightingales, black-birds, thrushes, whitethroats, garden warblers, tree creepers, chiffchaffs, wagtails, robins, tits and finches. The cuckoo is well described as a "cheerful cynic and self-indulgent worldling," seeming to make a mock of his musical gift. And so on through the different months of the year we saunter or lounge with these pleasant companions and note in a casual dreamy way the effects of the seasons on the garden beauty round about. If there is nothing to compare with an English spring and an English summer, and the beauty of an English autumn is unique, an English winter is best avoided by those who can, and therefore we naturally, but regretfully take leave of the author and his friends at the gate of "a rather mournful-looking manor house" as they speed softly away down the orchard drive on their way to Italy. Those who care for old houses and trees and beautiful gardens should read this book.

F.

**The weather in West Herts.**—As far as the present month has as yet gone, there have been only one unseasonably cold day and but five cold nights. The 16th was particularly mild, the maximum reading in the thermometer screen being 62°, which is higher than any temperature recorded here so late in November during the previous ten years. On the other hand, during the nights preceding the 18th and 19th the exposed thermometer registered over 9° of frost. At 1 foot deep the soil is now at about its average temperature for November. Since the beginning of the month over 3 inches of rain have fallen, which

\* "In Veronica's Garden." By Alfred Austin. Illustrated. Macmillan and Co.

is in excess of the mean fall for the whole month. Except on the first three days of the present month, the wind has come almost exclusively from some point between south and west, and on the 16th it blew with the force of a moderate gale, direction S.W. On the morning of the 18th the atmosphere was so foggy, that at 9 a.m. a house became invisible at a distance of 20 yards. Although one day was altogether sunless, the duration of bright sunshine for the past week averaged three and a half hours a day.—E. M., *Berkhamsted*.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee of this society was held on Wednesday last at the Royal Aquarium, Westminster. There was a good display of novelties, and some attractive exhibits were staged by Mr. H. Briscoe-Ironside, Mr. Norman Davis, Mr. E. Beckett, Mr. W. Wells, Mr. R. Owen, Mr. H. J. Jones and M. Ernest Calvat. Mr. McHattie staged two blooms of Mrs. W. H. Lees, one taken from the crown bud and the other from a terminal, showing the variety in two distinctly different forms, and was awarded a vote of thanks. A small silver medal was awarded to Mr. Briscoe-Ironside for a collection of cut blooms, which formed an important part of the meeting.

The following first-class certificates were awarded:—

**CHRYSANTHEMUM MME. A. CHATIN.**—Japanese, large and globular in build and of the incurving type, florets of medium width; colour pure wax-like white. Exhibited by Mr. E. Beckett.

**CHRYSANTHEMUM MISS ELSIE TERHMANN.**—Japanese, of good size, broad florets, curly at the tips; colour creamy white. Shown by Mr. E. Beckett.

**CHRYSANTHEMUM ROBIN ADAIR.**—A Japanese Anemone, with several rows of long, drooping ray florets; colour lilac-blush, centre tinted yellow. From Mr. R. Owen.

**CHRYSANTHEMUM BONNIE DUNDEE.**—Incurved. A deep solid flower of excellent form; colour golden-yellow, tinted bronze. Also from Mr. R. Owen.

**CHRYSANTHEMUM SURPASSE AMIRAL.**—A large Japanese with long narrow florets; colour golden-yellow. A seedling raised and shown by M. Ernest Calvat.

**CHRYSANTHEMUM MRS. HERMANN KLOSS.**—A very striking and large-sized Japanese with long flat florets; colour rich golden-yellow, suffused crimson. Shown by Mr. Norman Davis.

**CHRYSANTHEMUM KATE WILLIAMS.**—A long-petalled single-flowered variety; colour deep golden yellow. Exhibited by Mr. H. J. Jones.

**CHRYSANTHEMUM PARTHENIA.**—Japanese; long drooping florets, curly at the tips, and of medium width; colour white, slightly tinted. Mr. H. J. Jones was the exhibitor of this.

Other varieties were the new white Japanese Mrs. C. E. Shea, Latest Fad, an American novelty rather ragged in form, James Lynch, a good crimson reflexed, Graphic, Mr. Charles Lawton, and Desdemona. Jules Chrétien is a large, solid-looking Japanese incurved, amaranth and silver. M. E. Roger is a novelty of M. Calvat's, a green Japanese incurved of a decided hue. Harold Wells, a big primrose sport from Sir Trevor Lawrence, and many others were submitted for adjudication.

A meeting of the general committee was held on Monday last at Anderson's Hotel, Mr. B. Wynne occupying the chair. The secretary announced that prize money to the amount of £245 14s. was awarded at the recent November show at the Aquarium, and the following awards of medals were made by the arbitration committee: Gold medal to Messrs. H. Cannell and Sons, silver-gilt medals to Messrs. B. S. Williams and Son, Cutbush

& Son, Sutton & Sons, J. Veitch & Sons, and W. G. Tidy; silver medals to Messrs. W. J. Godfrey, C. Lee & Son, Spooner, N. Davis, the Jadoo Fibre Co. and Mr. T. Berridge; bronze medals to Messrs. D. W. Buchanan and H. Shoesmith. These awards were in each case unanimously confirmed. Some further discussion took place with regard to the lighting of the building on the evening of the show days. Mr. Harman-Payne presented the report of the catalogue committee relative to the proposed jubilee edition. It was suggested that a large committee of experts be invited to cooperate by sending in returns, as was done some years ago, and that these returns be examined and tabulated for the purpose of forming the basis of the new issue. Other additions, such as selected lists of early and hairy varieties will be made, and the catalogue is expected to be ready for the public early next autumn. Twenty-two new members and three Fellows were elected, making a total up to the present of 84 Fellows and 115 ordinary members for the year. A rough financial statement was submitted, and the jubilee fund of £1000 is now open for any persons who are interested in the society's great effort of next year to subscribe to.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 26, in the Drill Hall, James Street, Victoria Street, Westminster; and at 3 p.m. a lecture will be given by Mr. James Mason on "Asparagus Culture." The committees will meet as usual at 12 o'clock.

## NOTES OF THE WEEK.

**Hibbertia dentata**, a pretty late-flowering greenhouse climbing plant we noted in quantity in Messrs. Smith's nursery at Worcester, deserves to be more popular as a greenhouse or conservatory climber. It has large single yellow flowers, which in size and shape resemble those of a wild Rose, and the rich setting of bronzy green leaves contributes to the charming effect of the plant when in bloom.

**Acanthopanax crinitum** is a distinct and pretty Palm we noted in the St. Albans nursery. It has graceful, divided, arching leaves like those of a Kentia, but more slender, the under surface of the leaflets being of a decided glaucous green, a tint not common in this class of plants. The leaf-stalks are prominent also, as they are of a deep red colour and have red spines, each quite half an inch in length.

**The Macartney Rose.**—Since I wrote my note on the above Rose (p. 352) I have seen three good specimens in the gardens of Gnaton Hall, Yealmepton, near Plymouth. The largest covers a space of wall 10 feet by 8 feet and is growing very strongly, some of the shoots being as much as an inch in circumference. When once established it is evidently a fast grower even in England, and a Rose which, when better known, will doubtless be largely grown. At the foot of the Rose was growing a large plant of *Woodwardia radicans*.—S. W. F.

**Witsenia corymbosa** is an old plant not often seen in gardens, but Messrs. Smith, of Worcester, still retain it in their collection of plants, and a group of it now flowering in one of the cool houses in the Worcester nursery gives a welcome tone of colour at this dull season. In habit of growth this plant is very distinct, with leaves like those of a narrow-leaved Iris arranged in a two-ranked manner upon a branched woody stem. The flowers, of a lovely clear blue colour, are numerous, upon an erect branched raceme borne above the points of the pretty grassy leaves.

**Cimicifuga simplex.**—According to the new "Index Kewensis," the proper name of this plant, which is described by "H. P." on p. 371, is *Cimi-*

*cifuga foetida* (Linnaeus). De Candolle ("Prodromus," vol. i., p. 64) describes a variety, *C. simplex* (Wormst), as differing from the type in having a simple unbranched raceme, and as being found in Kamtschatka, the type being common in Siberia, Russia, and parts of the Austrian Empire. "H. P." describes the plant he saw at Kew as having branching panicles, so it cannot be var. *simplex*, and I regret that the names authorised by their own index are not adopted at Kew by those who label the plants.—C. WOLLEY-DOD, *Edge Hall, Malpas*.

**The Cornish Elm.**—Among the many and variable forms of the Elm there is probably none more deserving of the attention of the planter than this. It is a pretty tree, with a distinct pyramidal, erect habit of growth, and consequently easily recognised among other Elms, even in quite a young state. It is also a good town tree, and its upward habit of growth consequently fits it for street planting, for which purpose it is preferable to the wide-spreading Wych Elm, that has to be lopped into ugliness to keep it within bounds, and last, but far from least, its wood is exceedingly tough, and of high commercial value in consequence. Messrs. Smith, of Worcester, think highly of this Elm, and we were reminded of its usefulness and beauty by seeing the large stock of trees of this kind in their nursery. Both those who plant for ornament and for timber might with advantage plant the Cornish Elm more freely.

**Winter-flowering plants at Worcester.**—The middle of the planting season is not the most favourable time for inspecting a nursery such as that of Messrs. Smith and Co., of Worcester, which is mainly devoted to trees, shrubs and hardy plants of outdoor growth, and mostly now leafless and at rest. The glass department of this large nursery, however, is also extensive, and here during a recent visit we saw a number of useful flowering plants that serve admirably to brighten conservatories and greenhouses throughout the winter and early spring months. A batch of *Libonia penrhosiensis* showed what a bright and profuse-flowering plant this is, the red and yellow-tipped flowers glowing brightly among the leafy shoots. The old *Salvia splendens*, too, is still unsurpassed for brilliant colour at this, or indeed at any time. *Erica hyemalis* is too well known to need praise, but this and other kinds, well grown and abundantly flowered, contribute largely to the present gay display of bloom. These hard-wooded subjects are particularly well grown here. We noted quantities of *Epacris*, *Genetyllis* and *Pimelea spectabilis* in perfect health and vigour. *Cytisus racemosus elegans*, also grown largely, is a distinct plant alike in leaf and blossom, as it has long, pretty leaves of a silver-grey colour, and the flowers, already showing in the bud state, are as large as those of the Laburnum and rich yellow in colour. Other plants not now calling for detailed mention—being out of bloom—are the many stove and greenhouse climbers, all largely grown, and the whole stock of them first-rate. *Crotons* and *Dracenas* of a useful decorative size and highly coloured filled a large house, and another structure is devoted almost entirely to the noblest of all the Maiden-hairs—*Adiantum Farleyense*.

**Rose Catherine Mermet ss grown in Paris.**—Will anyone tell me how to grow Tea Rose Catherine Mermet in pots so as to have it a mass of blossoms and buds during November, as it is seen in the shops in Paris during that month? The plants are large and beautifully trained.—O. A.

**Names of plants.**—*Ina*.—Impossible to name from leaves.—S. B. *Pamford*.—Utterly impossible to name from the scraps you send.—J. B.—*Campanula carpathica*.

**Names of fruit.**—*Robinson*.—Pear Bishop's Thumb.—*Geo. A. Giblett*.—1, Rymer; 2, not recognised; 3, Hawthornden; 4, Hollandbury; 5, Pear Souvenir du Congrès; 6, Pear Fondante d'Autonne.

No. 1254. SATURDAY, November 30, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## STOVE AND GREENHOUSE.

### USEFUL PALMS.

It is hardly necessary to dwell on the value of Palms for decoration, the immense quantities now grown being sufficient evidence of their popularity. It would be quite safe to say that where ten years ago Palms were grown by the dozen they are now grown in thousands, and still the supply does not exceed the demand. Formerly a good many Palms were imported from Belgium, and at the present time some are still obtained from that source; but if their culture goes on extending in this country at the same rate as during the last few years, it will be quite safe to say that the Belgians will have to find another market for their plants. The Kentias undoubtedly take first place among Palms at the present time, and, considering the immense quantities now grown, one cannot help wondering what becomes of them, for they are not, like many plants, easily killed; indeed, under fair treatment they will thrive almost as well in a house as when growing in the stove. One great feature of the Kentias is that they are useful in any size, from tiny seedlings with about three or four leaves up to any size which can be accommodated. In a small state

KENTIA BELMOREANA is the best, and for large specimens *Fosteriana* is grown, as it makes a tall plant much quicker than *Belmoreana*. When raised from seed individual plants vary considerably. In selecting plants for growing on into specimens those with the recurved leaves should be selected. Some plants will be found with very dark leaf-stalks, and these are generally of good habit. Treatment makes considerable difference in the growth, as plants crowded together and grown in heat run up tall and thin. To have perfect specimens they must have plenty of room from the time they are first started, and although they will make plants quicker in heat, they may be grown successfully under cool treatment and will be more serviceable for decoration. Next to the Kentias named above,

COCOS WEDDELIANA is the most useful, and although it must be grown on in a stove temperature, if carefully hardened off it will stand well for house decoration. As a choice table plant,

GEONOMA GRACILIS is one of the most elegant Palms. *G. intermedia* is also very pretty, but few people succeed in growing the *Geonomas* into perfect specimens.

ARECA LUTESCENS, which before the Kentias came to the front was one of the most popular Palms, may still be regarded as indispensable, especially for tall specimens for using in groups. This Palm is now often grown in triplets. Three plants potted together when quite young form fine specimens. Generally one of the plants will take the lead, and the others, making weaker growth, form a good base. This Palm may be used for decoration, even out of doors during the summer, without any harm being done.

PHENIX RECLINATA, as an intermediate-sized plant, is a good Palm, being fairly hardy and of graceful appearance. It does not develop well-characterised leaves until the plants are too large for a 4½-inch pot, but in a 6-inch pot it is a fine plant. I prefer it to *P. rupicola*, as it is hardier and keeps its foliage better, not being liable to die off from the tips. *P. tenuis* is also a useful hardy Palm.

CORYTHA AUSTRALIS, though rather stiff in habit, is a useful hardy Palm. If grown in heat

and shade it will make longer leaf-stalks, which give the plants a lighter appearance.

LATANIA BORBONICA is extensively grown, and is most effective as a specimen to stand out by itself. Like the above, the character of the plants may be considerably altered by growing them in heat and under shading.

Of choicer sorts which are not so well known as those referred to above, some of the *Calami* may be included.

CALAMUS LONGIPES AND *C. INTERMEDIA* closely resemble each other, and both make very pretty table plants.

HYOPHORBE VERSCHAFFELTI may also be recommended, being very pretty in a small state, but a little stiff in a larger plant. *H. amaricaulis* may also be included.

LATANIA AUREA is another very pretty Palm. There is a variety of *L. borbonica* with yellowish leaves which is sometimes sold as *aurea*, but this should not be confused with the true species, which is of slender growth.

ACANTHOPHUXEN CRINITA is a very pretty Palm with gracefully arching leaves. Of this we get two distinct varieties among seedlings, some having dark reddish leaf-stalks and others pale green; in both the under surface of the leaves has a pale glaucous shade.

EUTERPE EDULIS is a very free-growing Palm and makes a light and elegant plant, but is too tender for general use.

RHAPIS HUMILIS is a very useful sort. This may be propagated by taking off the offsets from the base of the old plants, but this should not be done until the offsets have made some roots.

### CULTIVATION.

In growing on young plants, almost all of the Palms may be grown in heat. Provided a moist atmosphere is maintained, it is almost impossible to give Palms too much heat. For those who do not grow Palms in large quantities, it is better to procure young plants than to depend upon seed. In almost all instances the seeds lose their vitality in a very short time; in fact, it often happens that the whole of a large consignment perishes in transit. Last season I saw *Kentia* seeds which had evidently been in fine condition when collected, but which had been packed dry, and when the cases were opened every seed was found to be dried up. In all cases where seed is received, it should at once be put into moist fibre or moist sand. The large Palm growers sow the seed as soon as possible after it is received. In potting young Palms care should be taken not to damage the tap-root, or the plants will not start away well; this is especially the case with *Cocos Weddelliana*. For young plants good fibrous loam and sand should be used, and for larger plants a little manure may be added, and the plants should be potted firmly, taking care not to get them down too deep in the pots. I find it is much better to confine Palms to as small pots as possible. They are not only better to handle when using them for decoration, but will generally be found to keep in better health, for in large pots they are almost sure to get too wet at the root through the frequent syringing. After the soil gets wet and sour the plants will soon get into a sickly state. I believe it is a common error with many to think it impossible to over-water Palms. A moist atmosphere is beneficial, but too much water at the roots is quite as damaging to Palms as it is to any other class of plants.

In selecting Palms for decoration, those with leaves in a partially developed state should never be used, as these are very tender and easily damaged. If carefully hardened off, almost any of the Palms will do a lot of service

without suffering much, but to take them straight from a moist stove for one night will almost ruin them.  
A. HEMSLEY.

## HYBRID TUBEROUS-ROOTED BEGONIAS.

TUBEROUS-ROOTED Begonias, unknown 25 years ago, have now become so popular, that they may be seen in every garden. The parents of this race were *B. boliviensis*, *B. Pearcei* and *B. Veitchii*, introduced respectively in 1865 and 1867. If my memory is right, the first hybrid (*B. Sedeni*) was raised in 1869 from *B. boliviensis* × *B. Veitchii*; then in 1874 the red-orange-flowered *B. Chelsoni* was obtained from *B. Sedeni* × *B. boliviensis*. These two varieties had large, brilliant, nodding flowers, but not widely opened. In 1875-76 the true *B. grandiflora* arose in many colours with fully expanded flowers. In 1878 the true race *erecta* was obtained. It is from that date to 1885 that the greatest improvements were made amongst tuberous-rooted Begonias. Specialists, gardeners and amateurs set to work. Since that date the race has been considerably improved; the foliage is broader, closely set; the plants are dwarf; the flowers enormous, the average size being 4 inches to 5 inches in diameter, and the flowers quite erect. In some French nurseries one hundred thousand plants in all shades of colour can be seen in bloom in autumn. In the meantime, about 1875-76, M. Lemoine raised the first double variety, called *Gloire de Nancy*, which was soon followed by scores of others of various shades. Double Begonias are not sufficiently appreciated. When well grown their flowers are really marvellous, having the shape and size of a true double Balsam, whilst the finest varieties can be compared to a *Camellia*. Among seedlings, double and semi-double forms are produced; the former only have a real value. During the past few years tuberous Begonias have been somewhat neglected for bedding, *B. semperflorens* and varieties being substituted, but this is a temporary change. The persevering growers have not been idle, and have worked so skilfully, that they offer us now the following wonderful forms:—

### SINGLE-FLOWERED.

HYBRID TUBEROUS.—The first varieties obtained were slender, reaching 20 inches to 30 inches high, the flowers of various shades, spreading, horizontal or nodding, and more or less expanded, as stated above.

TUBEROUS GRANDIFLORA.—An improvement on the preceding, the flowers much larger, of nearly all colours; the petals very large, ovate, of great substance, quite flat when fully expanded.

TUBEROUS GRANDIFLORA ERRECTA.—This is the finest of the race. The plant is compact, bushy, the flowers quite erect, of very large size, overtopping the foliage, the largest noticed in France being 8½ inches across. These flowers are of nearly all shades, excepting blue and black. There are thirty distinct colours grown separately—fifteen true and fifteen false hues. A bed of perfectly true, erect, large-flowered Begonias is a grand sight, but it is under glass in a temperate house they form the grandest display and are the most conspicuous.

WHITE CENTRE FLOWERED.—This new strain has the flowers single, erect, of large size, the centre of which is shaded pure white. Up to this date this hue is to be observed only in red, light pink, dark rose, and salmon ground coloured flowers.

WIRY, OR IRON-STEMMED (*tige de fer*).—This name implies all varieties of single and double, which are dwarf, compact, with short, erect, rigid-flowering stems.

DWARF.—A selected strain of dwarf, bushy, large, single, erect-flowered plants, most suitable

for borders, edgings to beds, or for carpeting the ground under tall plants.

**STRIPED FLOWERED.**—This curious type was offered to the public a year or two ago. It reminds one of striped Azaleas or Carnations, the flowers being erect, large, and of good substance, elegantly striped on white, pale yellow, pink, deep rose, and carmine grounds. Shortly every shade will be included in the list.

**SPOTTED.**—An entirely new tribe of large, erect, single-spotted flowers. The aim of the specialist is to bring this race as perfectly spotted as *Gloxinia punctata*. Not to be had in the trade yet.

**BEARDED.**—This is a sensational novelty. The flowers are single, erect, large, of good substance. In the centre of each petal is a prominent, erect excrescence resembling a beard, of the same colour as the ground of the flower.

**PRIMULIFLORA, or PRIMROSE-FLOWERED.**—The flowers are single, erect, large, of a perfectly circular form, the four petals being of equal size and fringed exactly like a flower of *Primula sinensis* fimbriata. This race is still in its infancy, and will require two or three years before being brought to perfection.

#### DOUBLE-FLOWERED.

**TUBEROUS DOUBLE.**—The old strain with spreading flowers.

**TUBEROUS DOUBLE ERECT.**—Flowers very double, of great substance, of nearly all shades, perfectly erect. The plants affect a neat, regular bushy form.

**MULTIFLORA ERECTA (DOUBLE).**—This strain is truly one of the best improvements in florists' flowers of late years. They were raised in 1885 and sent out in 1890. The bulbs produce four to six slender short-jointed stems with small foliage, forming most beautiful dwarf, compact bushy tufts, covered with a mass of bloom from June until frost comes, from 6 inches to 12 inches in height. The flowers are small, very double and erect, lasting a long time. From their brilliant colours they are of the greatest value, I should say the best, for the flower garden. For pots they are useful. The cut flowers are much employed for bouquets. The leading varieties obtained are *Multiflora gracilis*, 6 inches high, the dwarfest; flowers very small, strawberry-red colour, the best for borders. *Aurora multiflora*, 8 inches high; flowers small, salmon or coral-red, dwarf and compact. *Mme. Louis Urbain*, 8 inches high, deep rose, very compact. *L'Avenir*, 8 inches high, bright cherry-red, very compact, one of the best. *Mme. A. Courtois*, 8 inches high; flowers creamy white, forms regular compact tufts, one of the best for bedding. *Lutea nana*, 8 inches high, clear yellow. *Henri Urbain*, 10 inches high, bright red. *Coquette de Clamart*, 10 inches high, bright deep pink. *Soleil d'Austerlitz*, 12 inches high, bright vermilion colour; flowers very small, extra. *Rosea multiflora*, 12 inches, pale rose. *Eugène Verdier*, 12 inches high, orange-red, flowers a little larger. *Lafayette*, 16 inches high, fiery red, most brilliant colour, the tallest. *Davis* (double) is a very fine variety, with brown leaves and bright red double flowers, both arising direct from the bulb, forming neat, dwarf plants 6 inches to 8 inches high. With the above colours it is very easy to form beds and borders of striking and most showy contrasts; in that case they are far superior to *B. semperflorens*, to which they ought to be preferred. They have the great quality of keeping their fine habit and regular form until frost. Even when planted very early they do not get shabby or outgrown, as many other tuberous sorts; they are of no value for winter-flowering. Their culture is easy, succeeding best when planted in the full sun, which is a special quality. Start the bulbs in April in soil in a frame, and give plenty of air as soon as vegetation commences. In May, plant in open ground 6 inches to 8 inches apart. Do not use a very rich soil; sandy porous loam, with a third or a quarter of leaf-mould, is sufficient. At the end of October, take up the bulbs and store them like

other tuberous Begonias. They are easily increased from cuttings.

**DOUBLE CHRYSANTHEMUM-FLOWERED.**—The petals of the flowers, which are quite double, have been changed into long, narrow, linear, spreading strips, giving the flower the appearance of a Chrysanthemum, nearly of all shades.

I believe the above list includes every form of tuberous Begonia known up to this date. Begonias will always produce a fine display when used in borders, on rockeries, and at the foot of the trees, provided these places are shaded or half-shaded. A bed of red, orange, or dark purple bordered with pure white produces a most striking effect. When grown in large pots they can be had in all their splendour, and are of the greatest value for the drawing-room, the windows, and the conservatory.

#### CULTURE.

Begonias prefer a very rich, light, porous soil (loam, leaf-mould, peat, and sand mixed in equal parts). Procure good sound tubers one or two (not more) years old; in February or March lay them on light soil (leaf-mould or cocoa-nut fibre) in pans or on a hot or temperate bed, under a frame or in a greenhouse, so as to start into growth; keep moderately damp. When the roots and the leaves are developed admit air until the middle of May and take off the lights. At the end of May when the beds are ready, take up the plants with the ball of soil attached and plant 12 inches apart. Give a good mulching of leaf-mould, cocoa-nut fibre, or Moss, and plenty of water during the summer. At the end of October cut off the stems, lift the tubers, take them into a dry, airy place, and a fortnight after they may be cleaned and kept dry, or placed in dry sand, in a frost-proof place until spring. The best and most active manure is blood mixed in small quantity with the soil before planting. On plants grown in pots it produces astonishing results. Begonias started into growth in March and planted in open ground at the end of May will look rather overdone in August and September, and so it is with zonal Geraniums; therefore careful gardeners have adopted the following system: They start the tubers in May, pinch the stems and the flowers until the end of July, getting in this way strong vigorous plants in August, when zonal Geraniums look overdone, or they take them up or throw them away and fill up the beds again with these prepared Begonias. This process ought to be adopted in every well-kept garden. Liquid manure and other fertilisers carefully and cautiously applied will prove most beneficial and increase the size of the flowers, chiefly on pot-grown plants. Do not be afraid of moving the plants about in the open ground during the summer; if plenty of water is given, the growth will be checked for twenty-four hours only.

#### PROPAGATION.

The easiest and quickest way is by seeds. In February, March or April fill up well-drained pans to within half an inch of the rim with fine soil, half peat and half sand, or half leaf-mould and half sand, the whole well mixed. Sow the seed rather thinly; do not cover, but make the soil firm with the bottom of a flower-pot or a piece of glass; cover the pan with glass and water through the bottom, never overhead. Place the pans in a stove, a temperate house, or on a bed under a frame close to the light. Every morning dry the sheet of glass and water when needed; in a few days the seed will come up thickly. As soon as possible prick off the strongest seedlings and plant them in other well-drained pans in same soil half an inch apart, keeping them at the same temperature. As

soon as these transplanted seedlings have filled up their room, replant them again into a more substantial soil into pans 2 inches apart, or on a bed 6 inches apart, under a frame, where they will stay until June, the time of planting them in the open ground. They will flower in July and make fine plants and tubers by October. When the season advances and the seedlings are getting stronger, air must be gradually and, finally, freely admitted under the frames. Tubers from sowings made after June are not sufficiently hardy to undergo the winter. Some gardeners start the bulbs in March, cut them into pieces (leaving an eye to each division) and plant them as adult plants. It is a barbarous and slow process which ought to be entirely abandoned, the plants being much inferior to seedlings.

New or rare varieties and the double ones are propagated from cuttings made with young herbaceous shoots from February to April. These cuttings inserted in sand, or cocoa-nut fibre, under glass, strike rapidly and make excellent plants for planting in the open ground in June. Some growers propagate them in summer. Three or four cuttings are inserted in August in the same pot and kept under a close cold frame, where they remain until starting time, but must be protected against frost in winter. These cuttings strike readily provided they are obtained with one or two eyes, and the bulbs produced are most valuable for spring planting, but do not expect a good result on more than fifty to seventy per cent. of these cuttings. Cuttings made with leaves will not strike. Open ground Begonias may be kept in full bloom until November if covered over with linen material; this covering must be put on every night and taken away every day if weather allows.

D. GUIHENEUF.

**Statice floribunda.**—This is one of the finest of the greenhouse varieties, but it does not seem to be so well known as it deserves. Growing side by side with *S. profusa* and *S. Butcheri*, it is certainly the best of the three. The leaves, which are ovate, have a crimson shading, which is more decided in the stalks and ribs. It is dwarf in habit and, as its name implies, very free-flowering. I first saw it at Messrs. Lee's Hammersmith Nursery a few years ago. I find this firm exhibited it at a meeting of the R.H.S. in 1883, when a first-class certificate was awarded. The *Statice*, like a good many other fine greenhouse plants, are somewhat neglected at the present time, but where they do get proper attention they make a fine show. Young plants are preferable to old specimens. Cuttings will root in a cool propagating pit, but a little bottom heat is beneficial. The cuttings should be taken off with a little of the old wood at the base, and put in singly into small pots, using sand and peat in equal parts. As the cuttings take some time to root, care must be taken, as they are liable to damp off. When well established they may be potted on, using a good portion of fibrous loam with the peat and sand. Plants propagated now will make useful flowering subjects for the following season. *Statice Holfordi*, a larger growing species which used to often be seen among specimen exhibition plants, is rarely met with now, though for the conservatory there are few plants which will keep up a bright display for so long a period during the autumn. I would much rather grow these old plants well than hunt up novelties of doubtful merit.—H.

**Berried plants.**—A wide interpretation seems to be placed on the term "berried plants" at autumn exhibitions. At Kingston, where six of these are invited, it seems to be the rule to show anything that carries ripe fruit, but whilst that leads to variety in a sense, exhibitors have the unfortunate habit of putting up their half dozens all of one kind; hence there is yet an absence of variety. The term "berried" seems to be wrong

when Capsicums of the long, red form well grown and fruited, the fruits ranging from 3 inches to 5 inches in length, were admitted. No doubt they were handsome, but, all the same, it is difficult to understand how these all come under the appellation "berried." Next came well-fruited plants of the erect, small-fruited variety, and third, some freely berried Solanums. Plants also of the pretty red-berried *Rivina humilis* were staged, and these undoubtedly do properly come into the category. They were, however, rather drawn, but well grown. Having compact heads, they should form some of the prettiest of berried plants for exhibition. Still, for all ordinary purposes, being semi-hardy, few plants seem to be more fitted for commendation than are good Solanums, for these will do well in a cool house, where Capsicums and tender plants would soon lose their leafage. No one, so far, seems to have shown *Skimmias*, perhaps because the limit of size of pot prevents sufficiently established plants being produced in good fruit. Without doubt these berried plants make a very pretty as well as an interesting class, but some more inclusive term than berried seems to be needed, and I think the best would be "ornamental-fruited plants," as thus enabling such things as Capsicums to be properly admitted.—A. D.

**The Begonia disease.**—I beg to thank all those correspondents who have written (in answer to my note) on this, and to assure them that the disease of which I complained is not caused by thrips or any other insect. Mr. Langdon may possibly know the disease, but I am led to hope not, as he does not describe it properly, for he speaks of the stems being first attacked, or first showing the effects, which then spread to the points of the shoots, while in my case, as I pointed out, the course is reversed. His cultural directions for prevention, too, are wrong, as the disease started in a house principally used for Ferns, and which always has a moist atmosphere, while outdoor plants, and a few others which had made all their growth in a light, airy and dry conservatory, did not suffer. I have had *Impatiens Sultanii* and other plants attacked by the little yellow thrips of which "H. P." writes, and know this insect and its work quite well. I am also able to see it easily with the naked eye. I am in the habit of using a magnifying glass in all cases of plant disease which are unknown to me and which come under my notice. The symptoms of disease mentioned by "G. C." are entirely my own, and boxes of seedlings have been attacked in a cool, shady frame this year. It is possible that steam from the pipes may encourage the disease in some cases, as the worst attack was on plants grown over the hot-water pipes, where drainings from the pots could not be prevented from dropping on them. I have no wish to foster a scare and hope the disease will not spread, but we have still something to learn about it.—J. C. TALLACK.

"G. C." (p. 365) says he had hoped to see an answer to Mr. Tallack's and Mr. Burrell's notes giving a remedy for Begonia disease. I grow *Begonias* largely, and was at a loss for some time to know what was the matter with the plants. On carefully examining them I found they were infested with yellow thrips, which begin their work of destruction on the stems and undersides of the foliage and fairly paralyse the plants. The best remedy I find is to fumigate the houses and frames with tobacco on the thrips first making their appearance, and again about three weeks later. By keeping a moister atmosphere I find the plants keep clean and healthy.—F., London.

**Sowing florists' flowers.**—From various causes many fail to secure a satisfactory germination of such seeds as *Primula*, *Cyclamen*, *Calceolaria* and similar small-seeded subjects. Sometimes, of course, the seed is at fault, but more often the method of sowing. It is quite useless to have much depth of soil in the pans or pots; better by far occupy more of the space with drainage, as, although very little water is needed until growth appears through the surface, the soil, if in too great a bulk, soon becomes sour. Fre-

quently the compost used for covering the seed lacks sufficient opening material, such as leaf-mould and silver sand; consequently it becomes too firm and prevents the seedlings coming through. From this cause the larger-seeded subjects, such as *Cyclamens*, are often crippled and deformed, even though they come through. I find it a good plan with the majority of flower seeds to cover the pans or pots with a square of glass and then to cover this thinly with Moss. This prevents evaporation and lessens the need for sprinkling. Occasionally, owing to the non-appearance of the seedlings at the proper time, one gets impatient, but it is best to allow time, as, if the seed is old or inferior in any way, several extra weeks will elapse before growth appears. At the beginning of September I sowed a pan of *Cyclamen* seed, and although it has been in careful hands ever since, the young plants are only just through the soil. When this is the case the best plan is to remove them from the intermediate house to a Pine stove or some such structure, where the lost time can be regained, removing them back again in due course. One of the chief points to be observed is not to give more water than is absolutely necessary either before germination takes place or while the seedlings are in a young state.—J. C.

## CHRYSANTHEMUMS.

### SOME NEW CHRYSANTHEMUMS.

At the floral meetings of the N.C.S. and at some of the trade displays there have been seen this season many excellent high-class novelties of quite recent introduction. The tendency is still towards monster blooms in the Japanese section, and probably the largest ever staged were the six magnificent white blooms of Mrs. H. Weeks sent up to the Aquarium on November 11. Next to these I should be inclined to place M. Ernest Calvat's new seedling *Australian Gold*, Mr. Godfrey's Mrs. Hume Long, and Messrs. Cannell and Sons' *Australie*. Raisers, with one or two exceptions, appear just now to be studying purity of tint, for the colours of many of the season's novelties leave little or nothing to be desired.

In the under-mentioned list I have given the names and a brief description to such of the novelties as seem likely to be successfully grown and shown in the future, although many fine varieties that a few years would have been hailed with satisfaction and kept in our collections for a long time are now-a-days pushed out of existence, not because they prove to be worthless, but because of the tremendous number of novelties that pour in upon us year after year.

**LE MOUCHEROTTE** (Calvat).—Very large, with long narrow florets, a Japanese variety, colour pure yellow, tinted bronze.

**M. AUG. LACVIVIER** (Lacroix).—A very fine drooping-petalled Japanese; inside colour salmon-rose, with reverse of golden rose.

**MME. CH. CHAMPON** (Calvat).—A large spreading Japanese; long, flat florets, colour white, shaded purple.

**M. G. MONTIGNY** (Calvat).—Japanese; of large size, but rather loose, very long florets, toothed at the tips, rosy white, streaked lilac.

**FLORIDOR** (Lacroix).—A Japanese of the incurving type, pointed florets, inside colour deep crimson, centre yellow.

**MISS ALICE LOVE** (Jones).—A Japanese; florets veined and ribbed, curly at the tips and of medium width, colour white.

**NOCES D'OR** (Calvat).—A Japanese incurved, with narrow or medium grooved florets, rich golden yellow.

**PRESIDENT ARMAND** (Calvat).—Very finely-incurved Japanese, with broad grooved florets; colour carmine-chestnut, reverse brassy yellow.

**EMILY SILSBURY** (Silsbury).—A large spreading Japanese, with long intermingling florets of medium width; colour dead white.

**PIGEUS** (Lacroix).—A perfect Japanese, with fine drooping florets; colour deep golden canary-yellow.

**M. CH. MOLIN** (Calvat).—Japanese; with flat reflexing florets, rather broad and pointed at the tips, yellow ground, shaded deep bronze.

**BOULE D'OR** (Calvat).—A very fine incurved Japanese, with curly and grooved florets of great breadth; colour golden amber.

**LADY ESTHER SMITH** (Owen).—Also of the incurved Japanese type. It has very long grooved florets and is a solid-looking flower; colour pure white.

**M. GEO. BIRON** (Calvat).—Japanese; something in the style of the Edwin Molyneux type, but more closely incurved, deep crimson, with golden reverse.

**M. BENJ. GIROUD** (Calvat).—A round drooping-petalled Japanese, not too large; also a deep crimson variety.

**Mlle. M. A. DE GALBERT** (Calvat).—Japanese, with broad florets, pointed at the tips; colour pure white. A large flower.

**REINE D'ANGLETERRE** (Calvat).—Very large Japanese; a loose flower of the Condor type, with flat florets; white ground, shaded rosy purple.

**MRS. CHARLES BLICK** (Blick).—Japanese, with narrow grooved florets, curly at the tips, large blooms; colour pure white.

**D. B. CRANE** (Jones).—A nicely formed incurved of the old type, a solid-looking bloom with petals of good substance; colour deep golden amber.

**EDITH TABOR** (Notcutt).—A beautiful variety of true Japanese form, long drooping florets, curly at the tips; canary-yellow, shaded lemon.

**JOHN SEWARD** (Seward).—Large Japanese with great length of floret, medium in width; fine canary-yellow, shaded lemon.

**MRS. J. SHURIMTON** (Seward).—Very large in size, a Japanese, having long florets, twisted at the tips; colour orange-yellow, streaked carmine.

**LADY BYRON** (Weeks).—Japanese incurved; large and globular in form, broad grooved florets; white.

**PRIDE OF MADFORD**.—A colonial seedling imported by Messrs. Cannell; broad pointed florets; inside colour rich rosy amaranth, reverse silvery amaranth.

**MUTUAL FRIEND** (Mann).—Japanese; very long florets, curly and deeply grooved; colour wax-like white.

**SOUVENIR DE TOULON** (Calvat).—Japanese incurved; very large, broad, grooved florets; colour pale amaranth, reverse silvery pink.

**MME. AD. CHATIN** (Calvat).—Large and finely incurved, of the Japanese type; colour clear white.

**AUSTRALIAN GOLD** (Calvat).—A monster Japanese with narrow florets, very full and double, canary-yellow, tinted lemon.

**KENTISH WHITE** (Cannell).—Japanese incurved of globular form, deep grooved florets, rather broad; colour pure creamy white.

**GEORGE HAIGH** (Owen).—A golden buff sport from the incurved Robert Petfield, which it resembles in other respects.

**MME. AD. MOULIN** (Calvat).—Japanese, with long drooping florets, large and deep in form, white.

**MME. PAUL LACROIX** (Lacroix).—Japanese; also very large, colour pale sulphur, passing to primrose.

**DEUIL DE JULES FERRY** (Calvat).—A rich and striking novelty in the Japanese section, long drooping florets, colour velvety violet amaranth.

**MRS. BRISCOE-IRONSIDE** (Briscoe-Ironside).—Japanese incurved; fine form, colour pale salmon-blush.

**M. CHENON DE LECHÉ** (Calvat).—Japanese, with reflexed drooping florets, centre primrose-yellow, shaded bronze, outer florets rosy.

**BARONNE DE BUFFIERES** (Calvat).—Japanese incurved; florets of medium size, pale lilac, reverse silvery pink.

**MAJOR BONAFFON** (Dorner).—An incurved, with a multitude of narrow pointed florets, pure yellow of rather a pale shade.

**OCEANA.**—Another colonial novelty, introduced by Messrs. Cannell. A fine massive Japanese incurved, with broad grooved florets, colour golden yellow.

**MRS. WEEKS (Weeks).**—One of the largest Japanese; very broad florets, curly, and intermingling, colour pure white to blush.

**MRS. HUME LONG (Godfrey).**—A large incurving Japanese; florets grooved and of great length, colour rosy amaranth, reverse silvery.

C. HARMAN-PAYNE.

### CHRYSANTHEMUMS AT SWANLEY.

SWANLEY has for many years been renowned as one of the places where the popular autumn flower receives a large share of attention, and Messrs. H. Cannell and Sons have on many occasions contributed important additions to our lists of select exhibition varieties. A week ago their large show house (160 feet long by 25 feet in width) was, and no doubt still is, a blaze of colour, all the good standard sorts being on show, besides a large number of the novelties for the present year.

Continental seedlings are an important feature at all the trade displays this season, and Messrs. Cannell are not behind other introducers in keeping their collection up to date. M. E. Calvat's novelties are in great abundance and are very highly thought of at Swanley, the principal varieties being *Souvenir de Jambon*, a Japanese incurved with medium-sized florets, chestnut-crimson, reverse old gold; *President Carnot*, of the same section, carmine-crimson in colour with a buff reverse; *Amiral Avellan*, a bright golden yellow Japanese, very rich and striking; and *Reine d'Angleterre*, a large, loose Japanese, colour purplish mauve and better in tone than we have seen it elsewhere. From the same raiser, Mme. Ad. Chatin, a white incurving Japanese, is good, as is M. Pankoucke, a fine yellow Japanese introduced last season. Mrs. C. Harman-Payne, M. C. Molin, Mme. Carnot, Mlle. Thérèse Rey, M. Gruyer, l'Isère, and several others prominently shown last season are also in excellent form. Newer kinds such as *Directeur Tisserand*, a yellow Japanese, suffused crimson; *l'Aigle des Alpes*, a Japanese with flat florets, colour reddish crimson, golden buff reverse; M. J. Ginot, a large spreading Japanese, deep rosy amaranth with silvery reverse, a fine flower; Mme. C. Champon, a rosy lilac Japanese, all promise to maintain the reputation of the raiser.

Among American kinds—which seem to do well this season, probably on account of the fine summer we have had—the far-famed variety *Philadelphia* must be mentioned. Here, as elsewhere, *Philadelphia* is not white, as was expected, but of a sulphur hue. G. W. Childs is very rich in bright velvet crimson, and of good size; Col. W. B. Smith, golden amber; Mrs. E. G. Hill, rather an early variety, pale blush in colour; and the newer *Major Bonaffon*, Japanese incurved with narrow grooved florets, colour deep golden yellow, are all striking in appearance. W. G. Newitt, pure white, is still worthy of a note. *International*, large Japanese, but not constant in colour, runs coarse almost everywhere; but in yellows, W. H. Lincoln and H. L. Sunderbruch exemplify the purity of tint so much prized by the transatlantic growers.

Two noteworthy varieties are *Eureka*, a large white Japanese raised by the Swanley firm, with broad florets, and *Sidney B. Levick*, a fine globular Japanese, with florets deeply grooved, rich reddish crimson inside, and reverse of golden buff. Well-known varieties like *Charles Davis*, *Avalanche*, *Sunflower*, *Rose Wynne*, *Vivand Morel*, and Mrs. Falconer Jameson are also grown well and in quantity. There are a few interesting seedlings raised in Australia and imported by Messrs. Cannell, all of the Japanese type, *Pride of Madford*, a rich tone of rosy amaranth with silvery reverse, being a conspicuous example. Another of these colonial seedlings is M. Van den Heede, a Japanese with long drooping crimson florets, the reverse old gold. *Oceana* is another, and al-

though only partly expanded at the time of our visit, bids fair to occupy a prominent position. It is a massive-looking Japanese, having broad, twisted, and curly florets, the colour a rich golden yellow. *Australie* is also a substantial flower; colour pale rosy amaranth, reverse silvery.

Among other novelties are some curious varieties bearing the native Japanese names, but these will be later in coming into bloom.

Incurved varieties are represented by *Baron Hirsch*, D. B. Crane, a golden buff, C. H. Curtis, fine yellow, *Globe d'Or*, and several others of older date; *Anemones* by *Descartes*, *Delaware*, *Junon*, and similar well-established kinds. In one corner of the greenhouse was a fine group of the new Japanese incurved *Kentish White*, recently certificated and described in *THE GARDEN* on page 349. *Pallanza*, Mr. Briscoe-Ironside's, golden yellow seedling Japanese, is also a fine addition to its class, and of a similar shade is M. P. Deswolfs. Mme. Sarlin is distinct, a Japanese, colour chestnut-crimson, with old gold reverse. *Kentish Yellow* is a Japanese reflexed flower, of a pretty pale canary-yellow.

A large portion of the structure is devoted to new seedlings raised by the firm. These are grown very dwarf the first year, or from 1 foot to 2½ feet in height, with only one bloom on each. Then the second year they are tried from cuttings and grown in the orthodox manner, by which means their value can be more readily gauged.

### CHRYSANTHEMUMS AT SYON HOUSE.

IN the fine collection of *Chrysanthemums* grown at *Syon House* all sections of the flower are well represented, the singles and dwarf bush plants as well as those bearing large show blooms. Good old kinds may here be seen side by side with the most recent novelties, and losing nothing by the comparison. At the present day newness of variety is allowed to weigh heavily in the judge's estimation, but it does not follow that the good kinds superseded are replaced by better ones. Plenty of evidence to the contrary can be gathered from any good collection grown in a private garden, as at *Syon*. Among those we noted recently in good form here are G. C. Schwabe, particularly rich in colour, quite a chestnut-brown, shading to rosy buff; *Hairy Wonder*, one of the best of its class, free in growth and bloom, with a good comparison in *Enfant des Deux Mondes*, a counterpart in pure white. *Louise*, a white incurved Japanese, was good, and *Beauty of Exmouth* charming with its long recurving petals. *l'Isère* has a pretty cream-coloured flower made up of long curled florets, and *Charles Davis* was noted for its richness of colour here. *William Holmes* is just the type of flower required in gardens, full, globular and bold both in appearance and colour, its crimson petals tipped with golden yellow. *Silver King*, of a lovely silvery pink colour, gives a welcome shade, and *Eda Frass* is equally as desirable, refined in form and of the tenderest pink colour. Col. Smith is evidently a kind that will stay long in private collections. It is a good grower, and, though showing much variation in form, always has good flowers of a rich and telling colour in any group. *Lilian Bird* has a unique flower. We have not seen it in any show stand this season, and perhaps it lacks size for that purpose, but in its own distinct and pretty form it stands out conspicuous from the lot. The petals are long and narrow, making a light starry flower of a soft mauve-pink colour. *Percy Surman*, an incurved Japanese of a rosy shade with silvery reverse, was good, and praise may be given W. H. Lincoln as a *Chrysanthemum* for all, however they grow it, large plants carrying a number of fine flowers here. Miss *Dorothy Shea* has loose flowers of a rather pleasing shade of chestnut-brown, Mrs. W. H. Lees was seen in good form, and *Amos Perry*, a clear soft yellow Japanese incurving towards the centre, is a new and very pretty kind. The true incurved forms were also well represented, the following all

having full fine flowers: *Robert Cannell*, Mr. Bunn, *Lord Alcester*, D. B. Crane, Mme. *Darrier*, *Baron Hirsch*, *Jeanne d'Arc*, and *Brookleigh Gem*, the last-named a handsome new variety bearing well-finished flowers striped with lilac on a white ground.

**Chrysanthemum Chas. H. Curtis.**—In my notes on new varieties at *Trent Park* (page 373) I made a mistake in regard to the above incurved sort. I intended to have included it among those at the time of my visit I thought promising, as it was then just unfolding its petals. The blooms in question finished remarkably handsome specimens, which were among the best exhibited by Mr. Lees. At one important show he obtained the award of premier incurved bloom in the exhibition with *Chas. H. Curtis*, thus stamping it a sort of more than ordinary value. I have also repeatedly seen it in good form lately, and although in some cases it has an unmistakable Japanese incurved look, it is a most desirable acquisition. The yellow is rich and its form noble. It is an English-raised seedling.—H. S.

**French show Chrysanthemums.**—The leading varieties, as evidenced by the season's show-boards—independent of the newly-introduced varieties of the present year—are Mrs. C. Harman-Payne, *Vivand Morel*, *Souvenir de Toulon*, Mlle. *Thérèse Rey*, *Etoile de Lyon*, *Boule d'Or*, Mme. *Carnot*, M. *Pankoucke*, Vice-President *Calvat*, *Deuil de Jules Ferry*, *Souvenir de Petite Amie*, Mme. *M. Ricoud*, *Van den Heede*, *Commandant Blusset*, Mme. *Ad. Moulin*, M. *C. Molin*, M. *G. Montigny*, M. *Bernard*, Vice-President *Audiguier*, *Alberic Lunden*, Mme. *E. Rey*, *Bouquet des Dames*, Mme. *J. Laing*, Mme. *Baco*, Mlle. *Marie Hoste*, President *Borel*, *Louise*, Mme. *C. Molin*, *Jules Chrétien*, Mlle. *A. de Galbert*, H. *Jacotot*, fils, Mme. *Ad. Chatin*, *Reine d'Angleterre*, *Mephisto*, M. *G. Biron*, M. *Ad. Giroud*, *Guirlande*, *Marquis de Paris*, Mme. *E. Capitant*, M. *Gruyer*, Mme. *Oct. Mirbeau* and *Beauté Toulousaine*.—CHRYSANTH.

**Popular show Chrysanthemums.**—Taking the winning stands in the chief classes at thirty-five of our leading shows, I find the following varieties may be considered as the most popular with exhibitors: Mrs. C. Harman-Payne, *Vivand Morel*, *Charles Davis*, Mlle. *Thérèse Rey*, *Edwin Molyneux*, Mme. *Carnot*, Col. *W. B. Smith*, M. *Pankoucke*, G. C. Schwabe, Wm. *Seward*, W. H. *Lincoln*, *Sunflower*, Mlle. *Marie Hoste*, *Duke of York*, *Miss D. Shea*, *International*, *Etoile de Lyon*, C. *Shrimpton*, *Deuil de Jules Ferry*, *Van den Heede*, *Commandant Blusset*, M. *C. Molin*, Mrs. *Falconer Jameson*, *Niveum*, and *Rose Wynne*.—CHRYSANTH.

**Hairy Chrysanthemums.**—Very few additions to the hirsute section appear to have been made this season, and most of those met with at the shows and at the trade growers are varieties of previous years. *Louis Boehmer* is one of the most plentiful. *Vaucanson*, somewhat deeper in colour and rounder in build, is still met with occasionally. *Perle d'Or* is new, but rather thin in the floret; it is a clear shade of pale yellow. *Papa Bertin* has long florets of tubular form, which are open and curly at the tips, colour pale silvery pink. *Hairy Wonder*, reddish bronze, is one of the best, and Mrs. *Alpheus Hardy*, the forerunner of this new group, has been seen large and well developed at several places. *King of the Hirsutes*, with long, tubular florets, colour rich golden yellow, and W. A. *Manda*, something similar in tone, also remain in cultivation. *P. Marieton* is new, a Japanese in form, large and solid, and of a golden bronze tint. *Enfant des deux Mondes*, or *White Louis Boehmer*, as it is sometimes called, is one of the best whites we have. *Esau* is well deserving of its name, for it is thickly covered with short hairs, and has tubular florets of a rosy amaranth colour. *Glasnevin* is deep purple-amaranth; *Prima Donna*, chestnut-bronze. *Sautel 1893* and *Souvenir de l'Ami Coye*, both white or pale blush varieties, are the only others I have seen worthy of mention.—C. H. P.

**ZEALS HOUSE, WILTS.**

ZEALS HOUSE is so called from the family of that name. In 1564 it passed into the Chafyn family till 1712, when the property became centred in the family of Grove by the marriage of John, son of Hugh Grove, of Chisenbury, Co. Wilts, with Mary, daughter and heiress of William and Mary Chafyn, of Zeals. This Hugh Grove was beheaded, with several others, by the Commonwealth on May 16, 1655, for his loyalty in proclaiming Charles II. King of England at South Molton, in the county of Devon. The room in which Charles II. is reported to have slept after the battle of Worcester is situated in the N.E. wing on the second storey, and is said to be in the same state now as when the king slept in it. The Elizabethan manor house standing on rising ground above an artificial lake, with its picturesque boat-house (as shown in the engraving), is occupied by Mr. Percy J. Browne as tenant of Mr. G. Troyte-Chafyn-Grove. Zeals House is not remarkable for fine gardens, though the effect produced by the judicious planting of trees makes the pleasure-grounds and park very charming. A fine avenue of Elms leads to the house on the north, and prominent amongst the giant specimen trees around the house is a

some extent I think this is the cultivator's own fault, the weather also being to blame, as for months we had much heat and little moisture. I think coarseness and poor quality are encouraged by early sowing in heat. From close observation for some years I have found the best quality and the greatest quantity of sprouts are obtained from plants raised early in March on a sheltered border. I do not say that Brussels Sprouts can be grown well on poor land without manure, quite the reverse, as in such seasons they suffer quickly if not supported with food in the way of good decayed manure. In stiff good loam there is less need of food and the plants are better able to resist drought, whereas in light soils such plants assume a bluish tinge and soon attain uneven proportions, the sprouts being poor and lacking solidity. Brussels Sprouts should never be less than 3 feet between the rows, and if a large variety is grown, a yard apart all ways is none too much. The smaller-growing kinds should stand quite 2 feet between each plant.

I never saw such a mixture of plants as this season, with great length of stem and few really good sprouts. In a quarter of a favourite kind—the Paris Market—I have a much larger variety mixed with it. I think it must be the imported, which at one time was most reliable. Now it is much too coarse and tall, and I do not advise its culture. The much-praised Aigburth

Onions was taken might be set aside for Brussels Sprouts during the coming year, the surface not being interfered with beyond clearing with hoe and rake, and drawing slight drills to plant in. Onions, being generally well provided for in the way of manure, the ground would be quite rich enough for sprouts, and its firm condition, while encouraging hard, fibrous roots, would likewise retain moisture better and have the advantage of a more even temperature. These conditions are essential for the production of good stocky stems of Brussels Sprouts in a variable climate like ours, another important point being not to sow the seed too early.—J. C.

**Spinach.**—Spinach will be scarce in this neighbourhood during the early months of next year, all late sowings having become badly affected with the "yellows." I usually manage by late and successional sowings to keep up a good supply, but shall have great difficulty in doing so this year. Seldom, indeed, is the loss so general, and one seems powerless to prevent these attacks in certain seasons, or to nurse the plants back into health again once they become affected.—J. C. TALLACK, *Livermore Park.*

**The Spoon Gourd.**—Whether this is a variety or a distinct species I cannot say, but I am inclined to think the latter. I have grown some scores of different Gourds, but I do not know of one at all like it. The seed is from America. Last spring I put out two plants on a few barrow-loads of fermenting material, with a small frame over them until it was filled, when the glass was removed. They have spread many yards every way, and the most remarkable feature about them is that they fruit at every joint even to the very points. These plants have had hundreds of fruit on them about the size of small Pears, of that shape, with an elongated end towards the stem, pale yellow, with orange stripes. The shell is of a hard, woody nature, like the Calabash. If cut longitudinally and the seeds and packing scraped out, it forms a spoon, which is used in America for such matters as would render the use of metal objectionable. The prepared specimen sent will show the fitness of its name.—J. M., *Charmouth, Dorset.*

*Zeals House, Wilts. Engraved for THE GARDEN from a photograph sent by Rev. J. A. Lloyd, Mere Vicarage, Bath.*

magnificent Tulip tree on the lawn to the east. The "nun's garden" to the north is a pretty little walled garden by the house filled with Ferns and many an old-fashioned and sweet-scented flower. The kitchen garden on the western slope is well planted and cared for, and contains several greenhouses and a small lake with pretty island in the centre. Zeals House contains many interesting relics of King Charles.

JOHN A. LLOYD.

*The Vicarage, Mere, Wilts.*

**KITCHEN GARDEN.**

**BRUSSELS SPROUTS.**

THESE this season are not all one may desire. The growth is coarse with open sprouts up the stem instead of the hard bullet-like growths so much appreciated. Of course this remark applies to private gardens, as I notice in market gardens there are better plants. This vegetable succeeds much better in some soils than in others, and my remarks as to field culture show that by having the crop more exposed, the sprouts are better, the plants hardier and less subject to insect pests. On the other hand, I have noticed that this season the growth is more irregular, and many growers have coarser plants with fewer firm sprouts. To

is too coarse, and in such seasons as this, when rain came and the soil was so warm, growth was very rapid and the distance given above would not be anything like enough. I have a grand lot of dwarf plants of Veitch's Paragon, which are covered to the soil with firm sprouts. These were sown in the open, but not allowed to remain too long in the seed bed; the quality and growth are all one can desire. These will remain good till January, when an April sowing comes in. The same remarks apply to Sutton's Dwarf Gem. This I have grown sown at the same time as Paragon, and am much pleased with it, the sprouts being medium-sized, solid, and of a nice green colour and splendid quality. I note these last-named varieties, as they are so superior in every way. The same remarks apply to Northaw Prize, a small grower, with closely-packed sprouts.—G. WYTHES.

On all hands one hears complaints of the tall, ungainly growth of Brussels Sprouts. I myself have visited several root shows and found this vegetable in each case unsatisfactory, the stems being furnished with large coarse sprouts instead of hard bullet-like knobs. I think good results might be made much more certain by treating the young plants much in the same manner as many treat winter and spring Broccoli, viz., planting not only on land free from fresh manure, but which has not been turned up for a considerable time. Where practicable, the plot from which this season's crop of spring-sown

**BOOKS.**

**THE POTATO.\***

OF late years there have been no noteworthy additions to Potato lore, and after such a thorough and exhaustive treatment of the subject as that before me, it is to be hoped it will be several years before other writers attempt anything of the kind. Mr. W. J. Malden has had a large and varied experience, and, unlike some of our professors, is actually engaged in cultivating the "noble tuber" on a large scale for the markets. It is not, therefore, a case of growing a few rods of Potatoes and using the estimate of returns per acre on what is done on such a puny scale. I do not for one moment dispute the accuracy of some of the reports on Potato trials, but they are misleading all the same. In the work under notice I fail to find anything that is misleading, but, on the contrary, the author carefully avoids exaggeration, never fails to point out where conditions have been favourable to the production of extra heavy crops as well as unfavourable to their growth, and not a cultural detail is omitted. As a matter of fact the work is at places rather too prolific, and would prove more acceptable and instructive if more concisely written. For instance, on p. 87 the following occurs:—

It is important that when Potatoes are cut they shall be planted within a very few days. If left in a heap they are liable to heat, which causes much injury to the young shoots. It is better, therefore, if from

\* "The Potato: In Field and Garden." By W. J. Malden. Published by the *Mark Lane Express*, 150, Strand, London.

any cause the sets cannot be planted at once, that they should be sprinkled with quicklime, which cauterises the cut portion and prevents waste of sap. Seed dressed with lime in this way is less liable to insect attacks. Liming is therefore a useful practice at all times.

All this is sound advice, but why go on to say—

It is highly important that cut seed be not left in large heaps, as it rapidly ferments. The chief injury arising from cutting is occasioned by fermentation, as the eyes are killed or weakened. Always spread cut tubers thinly about the floor of a barn if circumstances prevent their being planted immediately after cutting.

Better Mr. Malden had condensed his information so as to be able to present a book that could be sold at popular prices without impairing its usefulness. Again, who ever saw a Potato with haulm as shown in the illustration of Fidler's Colossal? It looks extremely like a plant of *Centaurea candidissima* perched on the top of a heap of tubers.

With Potatoes, as with fruit, the cry is for crops of superior quality, and, according to Mr. Malden, the losses owing to over-production—much of it inferior in quality—must have been very severe in 1893. Last year the natural outcome was a falling off in the acreage planted. Thus, the field crop of Great Britain was 504,454 acres, or 20,907 acres less than in the previous year. Even with this reduction it is found that, owing to foreign competition, the yields are more than can be profitably marketed, unless, indeed, disease, drought or frost intervene. Only those obtain high prices who grow Potatoes of superior quality, and it is in this direction and high culture, rather than increased acreage, that our farmers can hope to make their growth remunerative. The author premises this at the outset and never loses sight of it throughout his treatise. What he has to say with regard to foreign competition is to the point, and should be taken note of by those who, either from inexperience or want of knowledge of the real facts of the case, are constantly in the habit of taunting the farmer on his supineness. This is what Mr. Malden says on this portion of his subject:—

On the Continent large quantities of Potatoes are grown, the surplus beyond those required for home consumption being sent to England, and as water freight is so cheap, they reach the English markets more cheaply than many grown in England. It is often urged that English growers should prevent this importation by growing more, but this would not meet the case. As many as possible are sold at home, but those not required are exported, as it is the only way to turn them into hard cash. It is assumed that the profit is obtained on those sold at home.

According to Mr. Malden's experience, many generations of special treatment have rendered the Potato comparatively weak in constitution, therefore more liable to various kinds of disease, and there is much to be said in support of this theory. Holding these views, he naturally favours the substitution of newly-raised varieties for the worn-out older ones, and advises at length as to how to proceed in the interesting work of raising novelties of a really serviceable character. He is quite right in discouraging all haphazard selections of seed parents, as it is owing to indiscriminate crossings and the attaching of importance to one or two points only that have led to so many comparatively worthless varieties being introduced. To be successful we are told on page 13—

In variety-making it is important that the experimenter should be acquainted with all the features of the Potatoes he is going to deal with, otherwise much of his labour will be futile.

And the author further adds—

The points which it is most important to develop are vigour, power of resisting disease, and quality.

After treating upon soils and their preparation, all methods of planting, not omitting that known as the lazy-bed system, which is nearly or quite confined to Ireland, rotations and such like, this chapter being most comprehensive, Mr. Malden gives the results of some interesting experiments in the planting of Potatoes, more especially with

a view to proving which are the best times to plant. If these experiments could be regarded as conclusive, then comparatively early planting, or at the end of March, would be the best time to plant, completing the work by the end of April, but nothing of the kind can be proved in a single season. Experiments on somewhat similar lines that I conducted this year have been most contradictory throughout, and if they could be relied upon, horticultural instructors would have to modify their theories considerably. All such experiments, to be of real value, should extend over a series of years and be undertaken under a variety of conditions. Undoubtedly the month of April is a good time to carry out planting operations extensively, but some of the best crops I saw lifted this season resulted from planting late in May. From this we are led on to the study of manures, their application and effect, and the author has no hesitation in condemning the theory that soaking planting tubers in manurial solutions has a beneficial effect upon the crops. The remarks that follow on "seed," that is to say, planting tubers, are to the point, though I am somewhat sceptical as to the stated effect of washing tubers that are to be stored for any great length of time. It appears that if Potatoes are subject to a flooding of one day's duration they will inevitably keep very badly, this pointing to the necessity of lifting before we get floods in October, and of storing in raised rather than sunken "pits." That washing soil from tubers lifted in wet weather should lead to their rapid, wholesale decay, comes as a surprise. Years ago, when exhibiting was one of my weaknesses, all the largest and best formed tubers were invariably washed clean, well soaking in water, if necessary, to soften the soil, yet all these tubers kept admirably and were planted the following season. Varieties are discussed at great length, Mr. Malden only recommending what he has proved to be really deserving of commendation. Nearly fifty pages are devoted to "Diseases of the Crop," the life history, illustrated by numerous diagrams, of the most deadly, and the remedies for each being given. Spraying with the solution of sulphate of copper and lime, known as Bouillie Bordelaise, is considered the best disease preventive yet tried, and well worthy of general adoption. The chapter on digging Potatoes ought to be of special advantage to farmers, a variety of labour-saving machines and methods coming in for description and illustration, and there are also good practical hints given upon sorting, pitting, housing, and marketing. The yield of Potatoes in experimental plots has been at the rate of twenty tons and upwards per acre, but Mr. Malden has never seen more than "fifteen" (presumably tons) in open field cultivation, and believes that, owing to much unskilful treatment, the average throughout the country is less than six tons per acre. In the next chapter it is shown that the cost of producing and marketing the crops is, or ought to be, nearly £13 per acre, and at present low prices Potato culture cannot be very remunerative in any case, and must result in actual loss to the careless grower. Mr. Malden's excellent book on Potatoes ought certainly to be in the hands of every market grower, and private gardeners would find in it much that is interesting and instructive.

W. I.

**Heliconia illustris rubricaulis.**—Among the many new fine-foliaged plants that appeared in Messrs. Sander's group of plants at the Temple show, none attracted more notice than the plant above, whilst at the show of the previous year, when it first appeared in public, it was unanimously granted a first-class certificate. We lately saw a quantity of it in the St. Albans nursery, and whilst the leaves were as bright in colour as those of the plants shown in May last, some of them were of even larger size, approaching in dimensions those of a small-leaved *Musa*. It is almost impossible to adequately convey a description of the wonderful leaf colouring of this plant. The midrib of the leaf and the leaf-stalks

are bright vermilion-red, but the transverse venation and the subtle blending of several colours through the broad leaf-blade are wonderful.

## FERNS.

### GROWING IN PATCHES.

MANY market growers not only grow seedling Ferns on in patches of several plants together, but also double them again when potting on into 5-inch pots. This latter system, although it makes bushy stuff quickly, does not in all instances add to the beauty of the Ferns so treated. There are some which when grown on singly do not form such compact bushy plants as are required by the florists for decoration. These may be grown on from seedlings in clumps, and generally one plant will take the lead and grow tall, the weaker plants furnishing the base with shorter fronds.

In this note I did not intend to include ordinary market Ferns, but more particularly to refer to some of the choicer sorts, which when grown singly do not make much show. Instead of growing these on as referred to above I should recommend growing them singly until they have attained a fair size, then putting several plants into a shallow pot or pan. I find ordinary seed pans about 5 inches deep and from 8 inches to 12 inches in diameter are suitable for many sorts. They take about six plants of such kinds as *Cheilanthes elegans*, *C. tomentosa* and others of similar habit. Of course these may be grown on from single plants into fair-sized specimens, but the young plants grouped together have a better appearance. *Doryopteris ludens*, although it makes large bold fronds, is difficult to grow into a good specimen from a single crown. A most effective specimen may, however, be made by arranging a few plants together after they have made some good fronds, say about four plants in a 12-inch pan. *Pellaea ternifolia* is another which is easily raised from spores, but which, singly, takes a long time to make a good specimen. *Platyloma flexuosa* may be either grown as above, or if three plants are potted together in a 5-inch pot and suspended, they will make effective objects. *Pteris Victoriae* has proved disappointing to some, but if grown on singly from seedlings and then grouped together in pans it shows off to great advantage. I may here mention that though many growers do not succeed with this Fern, I have seen it growing as freely as the ordinary *P. serrulata*, really good plants being had in 5-inch pots. Some of the larger growing Ferns may also be treated in the same way with advantage. Take *Nephrolepis rufescens tripinnatifida* as an example. Old plants often produce stunted and distorted fronds, but when grown on from single crowns they under favourable conditions make very fine fronds. Single plants are too thin to produce a good effect by themselves. I might give many more examples, but the above will be sufficient to convey an idea of what may be done.

I have previously recommended raising seedlings to replace such as have become stunted with age, and I venture to suggest that if this practice were carried out to a greater extent than is done at present, the choicer Ferns would be more popular. It is not so difficult as many imagine to raise Ferns from spores; though some failures may occur, yet with care and perseverance most of the choicer kinds may be obtained, and the young plants will not give

so much trouble as trying to keep old and exhausted examples in good health.

The above remarks do not apply to such as the Tree Ferns, Cibotiums, and others, the fronds of which increase in size from year to year so long as the plants are kept in good health and are potted on as they require it.

**GROWING FERNS IN JADOO FIBRE.**  
THERE are few more ornamental and more generally useful subjects for conservatory decoration than Ferns. When, therefore, one comes across a specimen of this great family of more than ordinary merit, it is right to mention it. While on a visit to the charming

filled with Jadoo fibre. The accompanying illustration of *Gymnogramma schizophylla gloriosa* growing in a 7-inch pot in Jadoo fibre, and measuring 4½ feet across, shows how well Ferns will do in this material. True, the vigour, the robust health, and the fine colour of the fronds betokened

*Gymnogramma schizophylla gloriosa* growing in Jadoo fibre. From a photograph sent by Col. Thompson, Eastcliff, Teignmouth.

It not unfrequently happens that the small-growing Ferns get over-potted, while those of vigorous growth do not get so much pot-room as they require for their full development.

A. HEMSLEY.

garden of Col. Halford Thompson, J.P., of Eastcliff, near Teignmouth, I noted amongst other, and many, exceptionally good things a grand plant of *Adiantum cucuatum* suspended from the roof in an open wire basket

skilful culture, but the plant also showed the value of the material it was growing in. That this new potting material is particularly well adapted to growing Ferns in has been proved again and again. But its

special adaptability for hanging baskets is worth pointing out. For such a purpose it is much more suitable than ordinary Fern soil, because of its (1) lightness in weight, (2) rich and fibrous nature, (3) absorption and retention of moisture, (4) cleanliness to handle, and (5) its adhesive texture. Roots seem to ramify in all directions in Jadoo, and the fibrous roots of the plant, incorporating themselves with the material, make a cohesive mass which requires watering much less frequently, and when not over-watered does not drip, a great objection to hanging plants generally. In Col. Thompson's plant-houses this handsome West Indian Fern is far from being a solitary specimen of successful cultivation. As a matter of fact, the great majority of his plants are grown in Jadoo, and without a single exception all are thriving in such a way as to be a complete answer to anyone asking if this stuff is adapted for potting generally. His Chrysanthemums are the very pictures of health; the flowers are abundant, large, and possess an uncommon brilliancy of colour, while the foliage is of that deep green which may always be taken as a certain indication of good health in a plant. Heaths, Boronias, Azaleas, and many such hard-wooded subjects are doing splendidly in Jadoo; and so also are soft-wooded and tuberous-rooted plants such as Coleuses, Gloxinias, Richardias, Roman Hyacinths, Begonias, and others. Coming on in cold frames were Violets, Strawberries, Genistas, and many other plants, all doing equally well, thus testing to the full the capacities of the material for general purposes. Col. Thompson, as the patentee, is naturally proud of his success, and from the way in which Jadoo has been tested he has much reason to be.

A. HOPE.

## ORCHARD AND FRUIT GARDEN.

### PRUNING FRUIT TREES.

VERY sound and good practical advice has been given repeatedly on pruning, and how different kinds of trees ought to be cut to produce the heaviest crops of fine fruit, but situation, soil and other circumstances have so much influence on trees, that it is almost impossible to lay down any definite rules as to which is the correct mode of pruning. Beyond stating that sufficient room is necessary for all shoots and branches, avoiding any congestion of the growth or rubbing or crossing of the same, it is never advisable to recommend any particular system for any kind or variety of fruit trees without a full knowledge of their peculiarities on any particular soils or situations. Taking

#### APPLES

first, we have a number of varieties requiring special pruning to obtain the best results. Of these, Yorkshire Beauty, Mr. Gladstone, Irish Peach, Worcester Pearmain, Wealthy, and several more of that class always bear much the largest and heaviest fruit on the points of the shoots. There are other sorts that bear freely at the points of most of the short shoots. Amongst these, Branley's Seedling, Golden Noble, American Mother, Striped Beaufin, Lord Grosvenor and Lady Sudeley are notable examples; in fact, a long list of names might be given of such sorts, and wherever it is possible to leave those shoots that terminate with a fruit bud, I like to let them remain untouched with the knife, for if the blooms set, the weight of the fruit causes the shoot to have a weeping habit, and my experience is that the same is

covered its full length with splendid fruit buds for another season. It must be a very unfavourable spring if these buds fail to set and develop large handsome fruit. Some varieties, like Ecklinville Seedling, need scarcely any pruning beyond merely thinning out the growths, while rampant growers like Warner's King are more trouble to bring into a prolific condition early; but even the strongest growers can be made to produce good crops in suitable seasons by judicious management during the season of growth. The plan that I have practised (with excellent results) with these very vigorous trees is to rub out early all useless shoots, so that those remaining may have ample light, and when the pruning season arrives they are left practically their full length. The year following, these long shoots are covered with fruit-buds, which, as a rule, set so much fruit that thinning has to be done freely. Once get a tree to bear thus freely and no trouble is experienced in securing a crop afterwards, as a check is given to the growth by the weight of fruit produced. Here comes in another item of importance, viz., exhaustion, for though a tree may have been much too vigorous there is a limit to its strength, and a big crop may so weaken it that unless it is liberally treated fruit may be conspicuously absent for a season or two afterwards. As a case in point, I may mention that I had some young bush trees of Gascoigne's Scarlet Seedling that made shoots 6 feet long. These were left nearly their full length. The result was that last year the crop on the same was enormous and the admiration of all that saw it, but this year the trees have proved that the weight of fruit was beyond their power, as scarcely an Apple has been produced and the growth is much weaker. While writing of Gascoigne's Scarlet Seedling, I may state that it is a very fair dessert Apple, and will, I think, take its place as one of that class in the future. In pruning

#### PLUMS

it is a question if the knife is not employed too freely, and I believe that many of the deaths experienced in plantations of Victoria may be attributed to this cause. The trees must, of course, be kept within certain limits, or they would soon grow out of bounds. To stop this, a judicious system of stopping the shoots in summer acts admirably; if persisted in and no crowding is permitted, it is astonishing to see the mass of bloom annually on the trees. Gumming is practically absent, and owing to the increased light and vigour thrown into the fruit, it attains a size and colour seldom, if ever seen in the Plums from trees not summer-pruned. Some varieties, particularly Washington, appear to succeed and crop in the best form by the plan mentioned. Jefferson and Kirke's also answer admirably to the method, the fruit taking on a beautiful bloom, combined with size and rich flavour. The great difficulty I have experienced with the trees is that so much thinning of the fruit is necessary. In some seasons the frost has done it too freely, but in others it has been no light task. Plum and Pear trees on walls are often cut in more severely than is desirable to make them look well trained and models of shapely trees, but this is done in many instances at the expense of fruit. By this system of closely spurring in the growths, an unfruitful habit is acquired, and root-pruning is adopted with a view to improve matters, not always successfully. No doubt it is gratifying to hear visitors exclaim, "What a beautiful tree, and how well trained!" It would, however, be more profitable to have good crops of handsome fruit more frequently, and this may be brought about in many cases by

allowing more extension of the spurs and not being so particular about uniformity in the branches. If the spurs on Plum and Pear trees on walls are thus permitted to extend to a moderate length with no overcrowding of wood or foliage, trees that have been more or less barren previously will generally come into a bearing state. When the spurs become too long or unsightly, they can be cut out entirely to make room for others, or be shortened back half their length to form fresh shoots and fruit buds. Some practical men contend that the fruit is much larger from trees closely pruned. This may be correct on some soils, but I have not yet found it so, rather the reverse, there being always larger fruit and more of it. Of all wall trees,

#### MORELLO CHERRIES

are the most suitable for exact and formal training without any reduction in the weight of the fruit yield. The largest Cherries I have ever seen were grown on trees that were trained in the most careful manner, every shoot being as straight as a gun-barrel, and each one had just room enough to develop its foliage and no more, being also evenly distributed in every part of the tree; the result was a full crop of grand fruit annually from one end of the wall to the other. These Morellos and also the Sweet Cherries were always pruned before any other trees in the garden, and the capable old chief repeatedly stated that was the reason no gumming of the branches ever occurred. My experience of Cherries since then has borne out his opinion. On badly drained borders the result would probably be different, no matter when the pruning was performed. If possible, I like to have all pruning completed before the old year expires; this includes bush trees of all sorts, but the bird pest inflicts so much serious damage, that it is far from safe to do the pruning so early. Already these feathered enemies have seriously attacked Plum, Gooseberry, and Red Currant trees. Where large quantities of trees are grown, netting is out of the question. Shooting is much the same, as it is extremely difficult to shoot the birds without injuring the trees, and poison is against the law; therefore the grower can do little beyond fretting and fuming at the damage done almost under his eyes. I think £100 would not cover the loss caused by birds amongst our fruit trees last winter, and there are certain portions of the pruning that have always to be left until spring, so that we may try to save a few of the buds.

A word on pruning standard trees in orchards may possibly be of service now, as many will be commencing to overhaul their trees. I would specially urge the avoidance of the travelling pruner, who generally professes to be a thorough expert, and charges so much per tree for putting it in proper order, as he terms it. I have seen a number of these fellows in fruit-growing districts who ought to be never allowed to touch a tree with their implements of mutilation. Their main idea is apparently to saw out big limbs entirely, sometimes close up to the trunk, in others leaving a stump projecting a foot or more therefrom: in fact, doing the very opposite to what should be done. Many orchards of formerly healthy, vigorous trees have been completely ruined by this stupid and senseless treatment, and orchard owners in their own interests will do well to fight shy of such men. Supposing the trees have become a tangled mass of growth, some of the smaller and most congested branches should be removed, gradually thinning out the tops annually, until finally in a few years the heads are well balanced, and the air and sun freely admitted to every portion of the trees.

W. G. C.

## PEACH CULTURE IN THE OPEN AIR.

THE most successful Peach grower in the open air that I am acquainted with always prunes his trees in November. This is Mr. Pearce, gardener at The Cottage, Milverton, Somerset. In this garden is a wall with a south aspect that has been covered within the last few years with trees in the finest health, and that annually bear good crops of fruit. I wish to refer to the system of early pruning adopted by the cultivator I have referred to, because the practice is quite opposite to that pursued by the majority of growers, the early spring months being considered by them to be the proper time. The condition of the trees to which I have referred proves that it is as safe to prune in the autumn as in the spring. As a matter of fact, Mr. Pearce says it is better for the trees to prune directly the leaves have fallen than when the sap is just about to rise in the spring. The regular crops of Peaches which he secures show that he is not wrong in his ideas. It must not, however, be understood that this grower depends on early or skilful pruning alone for his crop. That is only one of the details of management which in all cases are regularly carried out. A thick mulch of rotten manure is laid over the roots as soon as the pruning is completed. This mulch is allowed to remain on the border until it is time to replace it with fresh material. There is no stint in this matter, sufficient manure being laid on to cover the border several inches thick. The disbudding of the trees in early summer, timely nailing in of the branches, and judicious thinning of the fruit, as well as syringing the foliage in the evening are all carried out at the proper time. Some growers may say that such treatment is not applicable in all cases. With such a statement I should not find fault, as I have had to unmail the branches in the autumn so as to get them away from the wall that the growth may get more air to ripen it. Such treatment is all very well in some exceptional cases, but I think it necessary in only a few. If, as in the case I am alluding to, the branches are not overcrowded, the wood will be ripe enough in the majority of seasons to be pruned in the autumn. It is the poorly nourished, indifferently managed trees, where the shoots are laid in so thickly during the summer that the leaves overlap each other, that produce unripe wood in autumn. It would, I am aware, be unwise to prune such trees in the autumn, but this does not furnish a reason why others more skilfully dealt with should not be attended to, especially when such good results are obtained by it as in the case under notice.

J. C. CLARKE.

**Plum Wyedale.**—At page 390 "W. G. C." speaks in praise of this most useful late Plum, and expresses a belief that it is not so generally known as it deserves to be. With these remarks I quite agree. There is also another old-fashioned Plum now little heard of and very seldom met with, namely, the Winesour. True, it cannot be said of this variety that it is fit for dessert, its flavour being rather too acid, but for tarts and general cooking it is invaluable during the latter part of October and early in November. When living near Birmingham I had a tree of Winesour under my charge, and I have kept fruit of it perfectly sound till November 20 by cutting some of the fruiting branches and inserting them into Mangold Wurtzels, placing them in a cool, dark place. Anyone contemplating planting a collection of Plums would do well to include a tree or two of each of the above varieties.—J. C.

**Gathering Pears.**—"Y. A. H." (p. 378) has some very suggestive notes on this subject. The effect of maturity on flavour seldom receives the

careful attention it deserves. A fine Jargonelle on a gable end was my first teacher on this matter. Its owner knew every phase in the development towards the highest quality in Jargonelle Pears, and could tell to an hour when to gather and eat them. This grower carried the gathering of his Jargonelles to the level of a fine art, and could tell when the most perfect time for eating had come. Of the Pears named by "Y. A. H.," I am best acquainted with Beurré d'Amanlis, Louise Bonne of Jersey and Marie Louise. Of the three, the Louise Bonne has the widest range of quality; the other two are more regular and constant under good culture and treatment. The great point—and it is by no means an easy matter—is not to gather Pears until they are sufficiently ripe to pack the fruit full of the sweetest sap and most luscious flesh of the highest quality, without allowing them to mellow into sleepiness. But very special knowledge and patience are needed to place every dish of Pears (so far as possible) on the table in the most perfect condition. The lists of dates of ripening for our most popular Pears and other fruits have proved somewhat misleading. Not only every county, but every garden and every parish would need a special dictionary of dates if the latter are to approach any degree of trustworthiness; and then the changing seasons would so destroy local data as to render them untrustworthy. Hence it often happens that the ability to know the exact time to eat Pears and other fruit is a more difficult art than their culture, storing, keeping and marketing.—D. T. F.

## CATERPILLARS ON FRUIT TREES.

THE Board of Agriculture, in a pamphlet dealing with caterpillars on fruit trees, and which has just been issued, says:—

There are several moths whose wingless females crawl up the stems of Apple trees in the autumn and early spring and deposit eggs in the interstices of the rind of the twigs and branches. From these eggs caterpillars are hatched in the spring, which eat the leafage and blossoms, and, in conditions favourable to their development, cause much injury to the fruit crop. Among these moths, the winter moth (*Cheimatobia brumata*) and the mottled umber, or great winter moth (*Hybernia defoliaria*), are the principal offenders. There are other moths of similar habits, as the scarce umber (*Hybernia aurantaria*), the great brindled beauty (*Phygalia pilosaria*), the small brindled beauty (*Nyssia hispidaria*), and the belted beauty (*Nyssia zonaria*), whose caterpillars injure fruit trees; but these are not nearly so common as the winter moth and great winter moth. In the beginning of October the winter moths and the great winter moths come from chrysalids in the ground, under and near the Apple trees that were infested with caterpillars in the preceding spring, and the wingless females crawl up the trunks of the trees for the purpose of egg-laying. The eggs of the winter moth are very small, cylindrical, and at first of a light green colour, afterwards becoming red. They are placed in small groups in the chinks of the rind, and fastened there with a sticky substance. From 150 to 200 eggs are laid by one female. The great winter moth lays larger, rather rusty coloured, long eggs, and more in quantity (as many as 400), which are placed in lines, or small groups, according to circumstances. From the eggs the caterpillars come in the early spring and, as it appears, just as the buds begin to burst. The winter moth caterpillars are at first grey, with dark heads, and so small that it is difficult to see them. Later on they become greenish, with white stripes and brown heads, and are finally rather yellow. When fully grown they are about three quarters of an inch long. They have three pairs of feet and move like other "looper" caterpillars, making loops with their bodies as they progress. They glue the leaves and blossoms together to form a shelter, and soon clear them off if the circumstances are suitable. When food fails, or when they are fully fed, they let themselves down to the ground by silken

threads and bury themselves in it. The moths begin to appear in the first week in October, and may be seen throughout November, and even December if the weather is fairly mild. The caterpillar of the great winter moth is chestnut-brown in colour, with a tinge of yellow on the under part of the body. It is much larger than the winter moth caterpillar, being 1½ inches in length. When the period of pupation arrives, the caterpillar descends to the ground and changes to a chrysalis just below the surface. In some seasons, especially in those when the progress of the leaves and blossoms is arrested by spells of cold weather, great mischief is caused by the caterpillars of these and other wingless moths. Sometimes the trees are left as bare as in winter, and are, besides, seriously injured for another season. The caterpillars not only attack Apple trees, but also Plum, Damson, Filbert, and Cob Nut trees, and occasionally Currant and Gooseberry bushes that are set under Apple and Plum trees in fruit plantations.

## METHODS OF PREVENTION.

It is very necessary to adopt methods of prevention against these insects. The first and most important of these is to prevent the passage of the wingless female moths up the trees in the autumn and winter months. This can be effected by putting sticky compositions round the stems to entrap the moths; or by placing an apparatus made of wood and tin, or other materials, such as stout varnished cardboard, to bar their progress. Fruit growers who have applied bands of sticky composition round fruit trees in a proper manner, and renewed them from time to time, have experienced great benefit from this practice. Cart grease made from fat or oils, and without tar, is recommended as the best and safest composition to use for banding fruit trees. It can be applied directly to the stems, but as constant greasing affects the bark, particularly of young trees, it is better to put it upon wide bands of tough, grease-proof paper, like that used by grocers, fastened round the trees with string or bass. When these paper bands are used for old trees the rough bark must be scraped away. Tar and some manufactured compositions have been found to injure the trees. If these are used they should be always spread upon bands of paper, and great care should be exercised in the selection and application of all compositions whose ingredients are unknown. Grease-banding must be commenced early in October, and renewed from time to time when the composition has become dry and hard. Bands made from old oilcask bags, or manure bags, smeared with sticky composition, may be used, but these must be fastened very closely to the trees, and frequently examined to see that the composition has not been absorbed. Hay bands have been employed for this purpose. There is, however, nothing so good as grease-proof paper. It will be necessary to keep the bands in good working order as long as moths are seen about. This will be quite up to Christmas, unless the weather is very frosty. In February or March, or as soon as frosty weather has gone, the wingless females of the other moths mentioned above come forth, and ascend the trees for the purpose of laying eggs upon them. These moths are not nearly so numerous as the winter moths, and it might not be necessary to keep the bands in working order for these alone, but it is desirable upon the breaking up of winter to note whether the male moths are flying about the trees in the dusk, and if they are seen in quantities to put the bands in working order. A guard is extensively used in the United States and Canada to prevent the canker worm (*Anisopteryx pomataria*), a moth of similar habits to those of the winter moth, from ascending fruit trees. It consists of a girdle of tin, fastened so as to slant 3 inches or 4 inches out from the trunk of the tree, held there by a circle of fine sacking or linen, and fixed by a cord, to which the sacking or linen is sewn. The tin is smeared inside all round with an offensive substance, applied with a small brush, which causes the insects to drop to the ground as soon as they come in contact with

it. In the United States a mixture of castor oil and paraffin is used. Soft soap used without water, and carbolic acid or paraffin would answer equally well, or cart grease and carbolic acid, or paraffin, could be applied. Another form of moth guard consists of a square box sunk some 4 inches in the ground round the tree, and so as to leave about 4 inches of space all round it, about 10 inches being above the surface. There is a zinc roof over the box, and under this there is a trough, in shape like the letter V, 2 inches deep, made of zinc. This is tacked on about 2 inches below the upper edge of the box and filled with paraffin oil. The moths get into the trough and are killed by the oil. To expedite the process of refilling the V-shaped trough with oil, and clearing it of the dead moths, and seeing that it is in order, it is arranged that the roof can be taken off by loosening one screw. This is a somewhat expensive guard, but it is said to be very effective. Upon some fruit farms, where banding is carried out, lighted lamps are also hung above tarred boards, placed near the fruit trees in order to attract and entrap the male moths, which in their flight sometimes carry the females up into the fruit trees. In the case of cultivated fruit land, many of the chrysalids might be destroyed by digging or hoeing the ground all round trees that were infested in the spring and by digging or hoeing in lime or gaslime. In grass orchards the grass should be cut off short and removed, or fed off by sheep close to trees that had been infested. The surface should be raked hard with long-toothed garden rakes, and beaten down with shovels to smash the chrysalids.

#### REMEDIES AGAINST THE CATERpillARS.

Spraying trees infested with caterpillars has proved advantageous in many cases where this process has been carried out well and adopted as soon as the slightest signs of infestation appeared. Small Apple, Plum, Damson trees and fruit bushes can be easily sprayed by means of ordinary garden engines fitted with long lengths of hose and fine spray jets to distribute the solutions over every part of the foliage. Large old Apple trees are beyond the reach of ordinary garden engines; to spray these, hand hop washing machines would answer, and there are machines especially manufactured for this purpose, fitted with strong pumps, and made narrow so as to go in fruit plantations.

The solutions recommended for spraying fruit trees infested with the winter moth caterpillars are:—

1. The extract of 7 lbs. of quassa, obtained by boiling quassa chips in water, to 100 gallons of water and 6 lbs. of soft soap.
2. The extract of 5 lbs. of quassa chips to 100 gallons of water, with 5 lbs. of soft soap and 5 pints of paraffin.
3. The extract of 4 lbs. of quassa chips to 100 gallons of water, with 4 lbs. of soft soap and 4 pints of carbolic acid, Calvert's No. 5.
4. 6 lbs. of soft soap and 2 lbs. of finely-ground hellebore and a quart of paraffin, boiled and well stirred. This is sufficient for 100 gallons of water.

Soft soap is dissolved in a tub with hot water. The quassa chips are boiled and put in a separate tub. Where paraffin is used it should be well stirred up or "churned up," as the Americans say, with boiling soap and water, before it is mixed with the cold water. Spraying must be commenced early, directly there are any signs of infestation, and as the hatching out of the caterpillars is not simultaneous, but may be extended over some days, the operations must be repeated when requisite. The solutions recommended above do not kill the caterpillars directly, but make their food and surroundings unpleasant and distasteful, so that they die of starvation or fall from the tree. In the United States and Canada, arsenical solutions are employed most extensively, and with remarkable effect, against the canker worm. They have not yet been adopted generally in this country on account of their poisonous properties, although, from some experiments made with them here, they have proved to be

most efficacious. There are two of these arsenical compositions. One, known as Paris green, is most strongly recommended by American and Canadian entomologists. It costs from 10s. to 1s. per lb. It should be obtained in the form of paste, which is safer than powder, and used at the rate of 1 lb. to from 200 to 280 gallons of water, according to the age and conditions of the leafage. If it is used too strong the leaves will be burnt. The solution must be kept constantly stirred so that it may be maintained of an uniform strength. It is not advisable to spray with arsenical solutions when the trees are in blossom unless the attack is very severe; in this case the solution must be made weaker. And as the object is not to dislodge the caterpillars, but to poison their food, the arsenical solutions should be made to fall like gentle rain upon the leaves, fine spray jets being used for this purpose. The other arsenical compound is London purple, which should be used in the same proportions as

*Gladiolus Lemoinei hybrids.*

Paris green and in a similar manner. It can be obtained in a fluid form and is as poisonous as Paris green. Live stock must not be put on Grass in orchards where arsenical compounds have been used until a considerable time has elapsed and rain has fallen. Such compounds must not be used where Gooseberries for early picking, and herbs and vegetables for early use are grown under the trees. Three or four days will elapse before the effect of the arsenical applications is apparent, and probably it will be necessary to repeat them in many cases. They can be put on with the same machines as those advised for the quassa, carbolic, and paraffin solutions. Spraying with Paris green, London purple, and other solutions prescribed for winter moth caterpillars would be also efficacious against the Apple blossom weevil (*Anthonomus pomorum*) and the Apple sucker (*Psylla mali*).

## GARDEN FLORA.

### PLATE 1042.

GLADIOLUS MRS. BEECHER AND  
G. BEN HUR.

(WITH A COLOURED PLATE.\*)

THE two handsome Gladioli represented in the accompanying plate are varieties of the race called *G. Childsi*, and along with several others were sent us for trial by Mr. J. L. Childs, of New York. It will be seen at a glance they bear a strong resemblance to the fine kinds that M. Lemoine has distributed within the last eight years, and which he obtained by crossing *G. Saundersi* with some of the robust and hardy forms of the *G. Lemoinei* section. At about the same Herr Otto Froebel, of Zurich, made a somewhat similar cross, *G. Saundersi* and a *G. gandavensis* variety being the parents. M. Lemoine classed the varieties he secured under the name of *G. Nanceianus*, whilst the progeny of Herr Otto Froebel's cross came out under the name of *G. Turicensis*. Previous, however, to the work of these two noted hybridists, Herr Max Leichtlin had crossed *G. Saundersi* and a variety of *G. gandavensis*, disposing of the varieties he secured to a French firm. These passed from France into the hands of Messrs. Hallock, of New York, and when that firm gave up business, although this new race had been greatly improved and fine kinds selected and named, none had ever been sent out, so they were purchased by Mr. J. L. Childs, who gave his own name to the family. This clearly explains the likeness that is manifest in the varieties of *G. Childsi* and of *G. Nanceianus*. The *G. Turicensis* cross seems to have been less prolific in fine kinds, but quite a large number are now included in the other two families.

Those of M. Lemoine's raising came first into prominence in England, as he was awarded a first-class certificate for *G. Nanceianus* var. *President Carnot* at a meeting of the R.H.S. held on

August 13, 1889. A coloured plate of two later kinds was also given in THE GARDEN of February 27, 1892. All who have grown the varieties of M. Lemoine's cross will find those of the *G. Childsi* section equally fine, free and robust. The distinct form, good constitution and other merits of *G. Saundersi* have passed into its progeny unimpaired, and as garden flowers we think these varieties better adapted to gardens generally than are the better-known hybrids of *G. gandavensis*, these latter being always somewhat uncertain. In a cold, adhesive soil the varieties that Mr. Childs sent us for trial did remarkably well. Both in wet and dry years they have given fine flower-

\* Drawn for THE GARDEN by Mr. A. F. Hayward at Gravetye Manor, Sussex. Lithographed and printed by Messrs. Joseph Mansell, Limited.

GLADIOLUS M<sup>RS</sup> BEECHER.

G. BEN HUR.

spikes and have increased at the roots as well, and we noticed most of them produced the little bulbils or spawn freely, so that on favourable soil they might be quickly increased and the best kinds grown to a large extent, as they certainly deserve to be. Although the spikes of these kinds do not have the great number of blossoms expanded at one time as are seen in many of the modern *G. gandavensis* varieties, what they lack in numbers they make up in size, the individual blooms of some sorts being nearly 6 inches across, fine bold flowers that are not in the least degree coarse, having that variability of outline, with pretty curves and reflexing of the tips of the petals, so characteristic of *G. Saundersi*. The quaint and marbled spottings in harmonious hues, so charming in this parent, have likewise been transmitted to its offspring. Two very fine kinds are those here shown, Mrs. Beecher being a brilliant crimson-scarlet, varied only by a few white markings on one segment. *Beu Hur* was perhaps the finest of them all as seen in the garden, and the spike figured rather falls short of the full beauty of the kind, its flowers being of great breadth of petal and strikingly beautiful in colour, a soft salmon-pink, flushed with darker colour in the throat. *W. Falconer* is another superb variety, having bold salmon-pink flowers, feathered with cerise-red. *Henry Gilman*, too, gave some tall and brilliantly effective spikes, its flowers being rich red, with a white throat and a narrow white line running down the centre of each petal.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**BROAD BEANS.**—It is not everyone that has glass for raising and hardening off Broad Beans in spring. For those who have not and yet wish for a few extra early dishes, the best plan is to sow now on a warm border, or well-drained open quarter well exposed to the sun. More care is needed than with spring sowings, the reason being obvious. Draw a good sized drill and half fill it with sweet loamy soil to which a little leaf-mould has been added. Let this be made firm and the Beans be sown rather thickly, as it must be remembered that mice are as troublesome amongst Beans as amongst Peas during the winter months. If sown thickly there will usually be enough in spring to fill all blanks and to make an additional row or two if desired. Cover with an inch of the same light loamy compost and finally with the ordinary soil. Do not afterwards leave them to take care of themselves, or in spite of thick sowings mice or rats may take every Bean in a few days. I do not advise the use of ordinary spit manure at this season, as the seed often rots if it comes into contact with it. If the ground is considered too poor without assistance, dig in some spent Mushroom manure. In regard to sorts for autumn sowings, none is better or earlier than the old *Mazagan*, but I like to sow a row or rows of *Green Windsor* also. This is very hardy, not easily affected by rot, and will even if the former variety succeeds form a good succession. I have known the *Seville Longpod* to be sown also with good results.

**SALADING.**—In many establishments salads will now be in great demand, and it behoves gardeners to take all the possible care of any Lettuces of the Cabbage section and surplus *Endive* left on the borders when the pits and frames were stocked, as it rarely happens that there is any too much left in those structures in March and April, especially after an indifferent winter. Those who possess a Peach case or orchard house may well utilise all vacant spaces in them by laying in both the *Endive* and Lettuce. If possible, give them a position pretty close to the front lights, so that by a free

and constant circulation of fresh air, damp may be warded off. It is very easy to blanch them by covering the plants either individually with flower-pots where not laid in too thickly, or by laying garden mats or even sheets of brown paper over them. Of course, the plants so housed must be used first, as at the approach of spring tree dressing and border surfacings will necessitate a complete clearance of everything from the house. When lifting secure as good a ball of soil as possible, as this makes all the difference. In regard to watering, it is best to soak the balls to settle the new soil round them after a few dozen have been laid in, as then the foliage can be held on one side and the water prevented from going into the centres. Many force or rather blanch *Endive* in the Mushroom house, and although this way is very convenient, the leaves are never so crisp as when kept in a comparatively cool place. Where *Chicory* is in favour a batch of roots may now be introduced into the Mushroom house, *Dandelion* being served in the same way. If these various subjects are used alternately they make a pleasing change in the salad bowl. All younger batches of the foregoing which are to be left in the open borders all the winter must not be neglected, or severe frost after a soaking rain may work irreparable mischief. Cover up nursery beds which are surrounded with boards furnished with cross rails with mats or canvas every evening when the weather looks at all threatening. Nothing surpasses dry leaves for protecting rows of the *Brown Cos* under south or west walls, this being proved by the green, fresh condition of those plants after a severe time which have been covered by mere accident by leaves drifted by the wind, uncovered ones by their side often being weakened or destroyed. The principal point to be observed in the management of all kinds of salads in the frameyard at this particular date is careful ventilation. It is always best to keep the lights continually tilted over the *Endive* frames in order to preserve the leaves in a dry state, as if near the glass 10° or 12° of frost will often damage them if wet. October planted Lettuce and Cauliflower, also Cabbages in frames, will now be all the better for a stir with a small rake, a sprinkling of lime and soot or soot and wood ashes also being necessary during the prevalence of such exceptionally mild weather, as slugs are both numerous and active. Remove all decaying leaves and avoid excessive coverings, or, indeed, coverings at all, unless the weather actually demands it.

**SPROUTING EARLY POTATOES.**—Where it is intended to grow a few Potatoes in pots it is now high time the tubers were placed in comfortable quarters to sprout. First of all place a small quantity of leaf-mould in the bottom, then stand each tuber on end with the most prominent eyes upwards, and set the box in an early Peach house orinery in a heat ranging from 45° to 50° during darkness. Moisten gently occasionally with the syringe, and as soon as the strongest sprouts can be detected remove all but the two most robust. In about three weeks tubers of *Sharpe's Victor* will be far enough advanced for planting in 10-inch pots. Under this treatment nice-sized Potatoes may be had for the dining-room in the early part of March. Some prefer boxes, and in such cases holes sufficiently large to allow of the escape of superfluous water must be bored in the bottoms. Through inattention in this matter the finer portions of the compost often wash down through the drainage, stopping the apertures and producing sourness in the soil. Where a variety of sorts is wished for, *Mona's Pride* and *Ring-leader* may be added to the above, as if the haulm should grow too tall, pinching may be practised. In purchasing seed tubers of *Sharpe's Victor* care must be exercised, as it is said that a spurious variety is being sold under that name. Owing to continued mildness, many sorts of early and second early Potatoes will be liable to grow unduly, especially where stored in cellars or root-sheds. They must be looked over now and then and all early sprouts removed.

**PEAS IN POTS.**—By the time these notes appear December will be upon us, and where pot Peas are

grown, a sowing should be made of such sorts as *William Hurst*, *English Wonder*, *American Wonder*, and *Chelsea Gem*. Use pots 10 inches in diameter and a fairly rich loamy soil, adding about a sixth part of well-decomposed manure. This quantity had better not be exceeded, or an unsatisfactory growth may follow, and it is an easy matter to apply artificial stimulants later on. Allow sufficient space at the top of the pots for earthing up when growth is 3 inches or 4 inches high, drain the pots well, giving them a light and airy position near the roof glass, and, if possible, not far from the ventilators. A house having a night temperature of 45° will suit them well for the present, and very little water will be required till growth appears.

**PREPARING FOR HOTBEDS.**—Where early Potatoes and Carrots are expected, say in April, no time must be lost in getting together such material as leaves, stable litter, and any loose littersy garbage from the rubbish heap, as it is quite astonishing what a bulk is required to build up a good-sized hotbed capable of accommodating three or four two-light frames. The beds will not be made up till Christmas, but, as a rule, leaves and manure are only forthcoming piecemeal, and plenty of time should be allowed for accumulation. It is advisable also, where plenty of shed room exists, to move under cover a sufficient quantity of suitable soil for planting and sowing these early forced vegetables in, as one never knows what the weather may be like when the time for that work arrives. J. C.

### HARDY FRUITS.

**DAMSONS AND BULLACES.**—These are well worth special mention where fruit is required in variety and quantity. Damsons are most useful in many ways, and may be grown where Plums will not thrive so well—for instance, in hedgerows or as dividing trees or nurses for choicer fruits. In my opinion the more these trees are exposed, the better they crop, and when grown in hedges the wood gets better ripened. In my younger days I had much experience of these fruits in the above form, and have never seen so good results with what may be termed trees grown in crowded gardens. The trees planted as advised will need little pruning or attention after the first season or two, the principal being staking to protect from wind. Of course, in private gardens variety in the fruits may not be required, but there is considerable gain in planting several varieties, as then the crop does not come in all at once. Again, some Damsons are better for cooking than others, and though the newer introductions are larger, they are not so free cropping. The old variety, or *English Damson*, is much grown in the midlands and is most prolific. The *Cluster* or *Crittenden*, a roundish, oval fruit, is excellent, both as regards cropping and quality, and also makes a good bush or pyramid tree; it also makes a fine standard, and grows freely when worked or on its own roots. The *King of the Damsons* is a large fruit, sweet and earlier than the above. It does well grown as a bush, and fruits freely in a young state. The *Prune* is much grown in the north and is of excellent quality. The *Bullaces* are valuable, as they give fruit after the Damsons are over. A tree or two should be in all gardens of any size. There are not many varieties, but the best are the new *Large Bullace*, which ripens its fruit at the end of October and is larger than the old variety, *Shepherd's Bullace*, a large green fruit, and the *White Bullace*, noted for its good qualities.

**QUINCES AND MEDLARS.**—These fruits are not much planted, and if space is limited they do well as ornamental trees on lawns or in shrubberies if not too much crowded. The *Quince* succeeds best in a moist situation. There is no fruit equal to the *Quince* for making into preserves. *Quince marmalade* is also excellent, and the fruit in a raw state is an excellent addition to Apple tarts, and keeps a long time if allowed to ripen thoroughly before gathering. There are three varieties—the *Apple-shaped*, a roundish fruit, quite yellow when

ripe and a sure cropper; the Pear-shaped, with green-coloured fruits, with softer flesh, later, and a little larger than the above; and the Portugal, a large fruit, late, and much covered with a woolly substance. This is a grand tree for effect, but not so productive as those named above.

MEDLARS come under the same heading as Quinces, as few are required. By some persons they are much liked, and form a useful addition to the winter dessert. The tree, like the Quince, is very ornamental, but will not grow in swamps. It likes a strong loam and does best in standard form. Many do not care for the fruits, as they require care in gathering and storing. If stored too early they are woolly and worthless for dessert. They require cool storage, and should be allowed to remain as late as possible on the trees. The Nottingham is the best flavoured and the tree is a dwarf grower. The Dutch is superior in size, the tree spreading and the fruits large, but not equal to the first-named in quality. The Royal, a newer variety, is good and a very free bearer, fruits large and superior to the Dutch. The trees should be little pruned, merely thinning out crowded shoots to admit light and air to the centre of the trees.

MULBERRIES.—I have a great regard for the Mulberry, as it has a noble appearance when aged and fruits so profusely. Little cutting or pruning is required, and the fruits in the early autumn are much liked for dessert. They also make a splendid preserve. I never knew trees miss a crop. There are only two varieties, the White and Black: both bear freely. I prefer the Black for dessert; the fruits are excellent when the trees are in an open, sunny position. The usual form of growth is as a standard, though the trees grow well in any form. Mulberries should be given good loamy soil, and in a young state require care in staking, as the wood is very brittle. This latter is a serious drawback to older trees, as they frequently lose large branches. Unlike many fruits, the old stems, if well banked up with soil, soon make new roots. When planting it is well to protect from cattle, the latter being fond of the young wood.

NUTS AND FILBERTS.—The leaves having fallen, these trees may with advantage receive attention. If at all crowded the trees should now be thinned in the centres, all sucker growths cut clean away, and the trees shaped if grown in the cultivated portion of the garden. These trees well repay good culture, and at times are much neglected. In places where these trees are much grown they are kept well thinned—in fact, grown in rows like huge Currant bushes and pruned annually. In planting it is advisable to get young trees from layers. They are more reliable than seedlings and soon fruit. The varieties are numerous, the best for garden culture being the Kentish Cob, the largest and one of the most prolific and a certain bearer; Webb's Prize Cob, a very fine type of Kentish Cob, the nuts being produced in large clusters; the Red Filbert, one of the best for flavour; the Kent Filbert; the Cosford, a smaller kind, but valuable when planted with others, as it produces a great quantity of male catkins.

FIGS.—Last winter having severely crippled many trees, more than ordinary care will have to be taken to preserve the new wood, as this will be soft. In a previous calendar I pointed out the importance of getting only a few strong shoots, and these as firm as possible. In no case do I advise coddling, as by free exposure as long as possible the wood will be firmer. With December close at hand, however, protection must not be delayed. The shoots should be unfastened from the wall, then tied together, and a good covering of dry Bracken placed round them. Failing the above, oat straw or loose litter may be used. Secure to the walls and cover with a mat, this giving a neat finish to the trees and preventing them blowing about. Very old trees that are not covered are often fruitless because the points of the new wood are killed. Young trees or those with new wood from the base should have a good thickness of litter to protect the stems and surface roots.

PLANTING FRUIT TREES.—With copious rains the soil is in fine condition for planting. The work should be proceeded with without delay, as trees put in now will give less trouble if a dry summer follows. In heavy land it is advisable to add additional materials to lighten the soil, and such aids may be prepared in the way of burning all kinds of garden refuse, collecting road scrapings where obtainable, and any old mortar or brick rubble. In light soils the addition of clay, loamy turf, or old Melon beds will greatly assist the fruit trees to make better wood and remain healthy for years without recourse to root-pruning. In no case plant deeply; the collars of the trees should be kept above the level, as with mulchings and soil given at intervals the trees will get too deep. Plant firmly, in dry weather if possible, and do not expose the roots to drying winds.

G. WYTHES.

### NOTES ON PLUMS.

THE following notes on Plums which we are enabled to publish through the kindness of our correspondents will doubtless prove interesting to our readers. They are from all parts of the United Kingdom. The following are the questions which we submitted:—

1. *The value of the Plum as an orchard tree, and how far its culture deserves extension, and in what soils?*
2. *Your opinion as to the value of new Plums, including those of Japanese, American, or European origin?*
3. *The best flavoured Plums?*

The Plum is largely grown as an orchard tree in this neighbourhood, but the varieties are poor, with the exception of Victoria and Belle de Louvain. The market growers depend upon Orleans, and what is known as bastard Green Gages. The latter are the result of taking suckers from other trees and growing them on without grafting or budding. They crop freely and the fruit fetches a fair price, but the quality is exceedingly poor. Plums succeed best in sandy loam overlying clay, but at some depth from the surface. When the crop is a very heavy one prices are low, and the fruit hardly pays for the picking. Belle de Louvain, Pond's Seedling Jefferson, Bryanston Green Gage, Diamond, Gisborne's, Prince of Wales, and Monarch are a few deserving varieties. Jefferson is, in my opinion, the finest of all Plums for jam-making, superior even to Green Gage. As a cropper it is unrivalled, either in the open or against a wall. Washington is another variety that succeeds here admirably against an east wall. Against a south wall one large tree stood for ten years and never bore a crop, in spite of judicious root-pruning. It gave a yearly crop of blossom, the tree all the while being the picture of health. From trees on the east wall I get yearly crops of very fine fruit, and of excellent flavour. Green Gage, Washington, Coe's Golden Drop, Jefferson, Kirke's, and Transparent Gage are all good-flavoured varieties. — E. MOLYNEUX, *Swanmore Park, Bishop's Waltham.*

The Plum is no doubt one of our most useful fruits, and should be extensively cultivated in suitable districts. It is not largely grown in the immediate neighbourhood, although most cottage and farm gardens have some trees, generally of the commoner and harder sorts, such as Victoria, Winesour, Orleans, Bullace, and Damsons. Gages and other choicer sorts are also sometimes met with. In this garden Plums do not do so well as most other fruit. I attribute this to the soil being on the sandstone rock, and consequently deficient in calcareous material. No doubt it could without much trouble be made suitable, and when time permits I intend taking up Plum culture more fully. The most suitable soil for the Plum is that on calcareous rocks. It likes a thin soil, and should be grown on the hill slopes to the south, and have shelter from the north and

east. In these situations its fruits most abundantly. A gentleman who cultivates this fruit largely not far from me says that half standards or bush form of tree planted rather thickly succeed the best. Victoria is one of the hardiest and greatest bearers. Early Prolific also does well, as well as Orleans, Jefferson, Mitchelson's, Pond's Seedling, and Damsons of sorts. I cannot say much as to new Plums, but those of European origin seem to do best in this district. Jefferson and Washington, of American origin, are good Plums, but require to be grown on walls. I consider some of the best-flavoured Plums are the Gages, Jefferson, Coe's Golden Drop, and Washington.—J. S. UPEX, *Wigganathorpe, Yorks.*

As an orchard tree, certain Plums are valuable when good soil can be had. They will pay well for their cultivation around here. Where they do best is on a good, retentive loam, where no water lodges. I grow most of the Green Gage class, as they are what my employer most cares for. I include Denniston's Superb. MacLaughlin's I consider one of the best flavoured Plums grown, equal to any Green Gage. For flavour, Green Gage, Transparent Gage, July Green Gage, Late Green Gage, Bryanston Green Gage, Brahy's Green Gage, with MacLaughlin's and Denniston's Superb are what are most sought after here, although I grow several other sorts; but as long as I can supply the above they are not inquired for. In the orchards around here Wine-sour and Victoria are grown a good deal.—A. HENDERSON, *Thoresby.*

When one sees the market glutted with Plums most seasons, and these such a perishable fruit, it does not seem wise to extend their culture as an orchard fruit, though perhaps their season might be extended by having some earlier. Plums do well in many soils, some very good fruit being grown here in a poor, chalky soil. New sorts I have no experience of, and the best flavoured undoubtedly belong to the Gage family.—J. HILL, *Braham Gardens, Cambridge.*

I consider the Plum the most valuable fruit we have for orchard culture, and when the soil and situation are suitable it deserves extension. Light soils I do not consider suitable for Plum growing. A strong or chalky loam is, in my opinion, the best.—J. SMITH, *Mentmore, Bucks.*

Plums would, in my opinion, do better and be much more remunerative in many orchards than the Apple trees one usually sees in a half-decayed condition, occupying much space to no purpose. Many soils that the Apple refuses to do well in would grow Plums to perfection. Especially is this so in this locality. Cox's Emperor, Black Diamond, Pond's Seedling, Victoria, and various other kinds are all capital sorts, and would do well in most orchards. Among the best-flavoured kinds are Angelina Burdett, Jefferson, Kirke's, Reine Claude de Bayay, and Transparent Gage.—W. NASH, *Baldminton Gardens, Chippingham.*

The only Plum I am acquainted with deserving of orchard culture in this neighbourhood is Victoria. It is most fruitful on light soils, but I have had it bear abundant crops on our heavy clay. The best-flavoured Plums here are Green Gage, Jefferson, Kirke's, and Victoria, the last sometimes very good on walls.—J. SHORT, *Hammersknott, Darlington.*

As to the value of the Plum as an orchard tree opinions differ. In certain seasons good prices are realised. In some seasons the whole prospect of the season is shattered by frost when the trees are in full bloom, while in another season the Plum crop is so abundant that the markets are glutted, and the fruit does not pay for gathering. I have known instances in Worcestershire where the Plums have been allowed to drop off the trees, and pigs have been turned into the orchards to eat them up. This neighbourhood is not well adapted for the growth of the Plum, the soil being too light and sandy and overdrained. I get good crops, but not size. As to sorts, Victoria is the best orchard tree. Prince of Wales, Autumn Compôte, Rivers' Early, Kirke's, Diamond, Cox's Emperor, Pond's Seedling, Prince Englebert, Jefferson, and Green

Gage are amongst the kinds that succeed best with me. Jefferson and Green Gage are the best flavoured. The best soil for the Plum is undoubtedly light to heavy loam, resting upon a gravel or limestone subsoil.—G. BLOXHAM, *Brick-hill Manor, Bletchley.*

I have some Plums growing here in a stiff clayey soil as orchard trees, such as Autumn Compôte, Bryanston Gage, Coe's Golden Drop, Coe's Late Red, Damsons of sorts, Diamond, Kirke's, Early Favourite, Jefferson, Large Black Imperial, Mitchelson's, Orleans, Pond's Seedling, Victoria, Washington, Winesour, &c., and they do very well. I find the best Plums for flavour to be the Gages of sorts, Jefferson, Reine Claude de Bayay, Transparent, and Ickworth Impératrice. These are hard to beat, especially when grown on a wall.—THOMAS SHINGLES, *Tortworth, Fulfield, Gloucestershire.*

## ORCHIDS.

### DENDROBIUM PHALÆNOPSIS SCHROEDERIANUM.

THE introduction in quantity of this grand Orchid should mark quite an era in Orchid growing, no other known kind being so attractive during the winter months. The beautiful racemes, so richly coloured and withal so refined and graceful, have a charm peculiarly their own, and the more one sees of it the greater the desire for it seems to be. But with this distinctness there is sufficient variety to arouse interest in the opening flowers, not only in colour, but to a certain extent in the shape also. The lip varies considerably in this latter particular, some forms having the front lobe narrowing almost to a point, while in others it is very full and rounded, the latter being much preferable. The blossoms are produced with the greatest freedom, the old, dry-looking stems contributing their share to the display in addition to the spikes produced from the tops of the young growths; indeed, it is not unusual for the plants when newly imported to push flower-spikes before any other signs of life are apparent, and though this would appear to be detrimental to them, I could never see any difference in the after-behaviour of these plants from that of those that did not produce them, though perhaps they may not start quite so quickly. This tardiness in starting is, however, a characteristic of the species, and months will often elapse before any roots or growths appear. The basal eyes would seem to be easily injured and rendered blind by the drying consequent upon importation, or perhaps by the cold to which the plants are exposed, and the plant has to form others before an outlet for its energies is found. As this is as often as not some distance up the stem, it is better not to place the plants in pots or other receptacles until they do start, otherwise the roots when produced will be far out of the reach of the compost. In the case of newly-imported Dendrobiums I prefer laying them flat on a moist stage to hanging them up in the house, and for this kind I believe there is no better plan than laying the plants upon Sphagnum Moss kept regularly moist, without being saturated. As mentioned above, the plants will probably be a long time in starting, but when once they begin to grow freely, no time should be lost in getting them in place. In choosing their home, it must be kept in mind that the roots, though freely produced, are not of an ambitious nature and do not, as a rule, run very far from the stem, but prefer to grow closely matted together, twining around and interlacing each other. This being so, it is evident that a large pot holding a good deal of compost is not only unnecessary, but

really harmful, the roots not being able to penetrate it and gain a hold on the sides of the pots. The smaller their circumference then, provided the plants can be got into it, the better, and for the same reason the layer of compost must only be thin, and should contain abundance of small crocks or similar material to prevent closeness. If necessary, to bring the base of the young growths into contact with the surface of the compost, the stems must be cut through an inch or two below them and brought down, or they may in some cases be bent sufficiently to answer the same purpose. Place them to form as neat and well-balanced a plant as possible, and then fill up with the compost, making the latter firm to prevent the stems rocking about, and using a few stakes if these seem to be needed. Care when potting must be taken that the young shoots are not broken off, for they are very brittle. They are also very liable to damp, so attention is needed in watering until they become strong and are rooting freely. This Dendrobium should be grown in the warmest house all the year round, and rested simply by partially withholding the water supply. The typical *D. Phalænopsis* was introduced from North Australia in 1880, the present variety, as is well known, having been imported by Messrs. Sander and Co. about four years ago from New Guinea. R.

**Odontoglossum Oerstedii.**—When well grown this is a charming Orchid, the little flowers having a novel and distinct appearance at once chaste and effective. It requires careful treatment to do it well, but this it well repays. The best of all modes would undoubtedly be on lightly dressed blocks of cork or teak, but this necessitates so much attention to watering, that we have to fall back on pots or pans. The latter are preferable, and they should be broad and shallow, suspended as close to the glass as possible. Fill these nearly to the rim with crocks, raising a little towards the centre, and wire the little plants down firmly upon a cushion of Moss and a very little of the best peat. With the dibber press this well about the bases of the pseudo-bulbs, so that they may root easily into it and keep steady, trimming off all ragged and protruding ends. A full supply of water is needed all the year round, but after repotting, care is, of course, necessary. *O. Oerstedii*, a native of Costa Rica, was introduced in 1872, and the flowers occur on short racemes of two or three, each being about 1½ inches across, pure white, except a yellow stain on the lip. The variety *majus* has larger flowers than the type.

**Odontoglossum Inseleayi splendens.**—This differs from the type in bearing larger flowers, which are more richly coloured, the better forms ranking amongst the most brilliant of the *O. grande* section. Many plants produce four, or even five, flowers upon the spike, each being nearly 4½ inches across. The sepals and petals are of a rich tint of brown, margined and heavily tipped with yellow. The lip is broad and clear golden yellow in colour, while around the front and side lobes is a distinct margin of large crimson spots. There is also a form of this with clear golden yellow flowers, with no markings save a few light splashes of brown about the crest and the marginal spots of crimson on the lip. All the varieties are natives of Mexico, and are better for a little more heat than the crispum and triumphans section.

**Epidendrum polybulbon.**—A well-grown plant of this tiny Orchid is very attractive when covered with the pretty little purple and white flowers. It would appear to be a very widely distributed plant in Jamaica, Mexico, and various other parts of America. The plant is of a creeping habit, bearing small two-leaved pseudo-bulbs at intervals upon a wiry rhizome. The habit of the plant at once suggests the kind of rooting medium and receptacle required, flat pans with only a thin layer of peat and Moss answering

admirably. The little bulbs should be pegged down to admit of their rooting into the compost freely, and when they reach the edge of the pan they may be easily bent back, thus keeping the specimen well furnished with flowering growths. A little fresh compost will be required annually, and any decayed and worn-out pseudo-bulbs must be removed at the time this is applied. If the pans are well drained and the compost in good order, frequent supplies of water will be needed while the growth is being made, and at this time the plants may be in the Cattleya house. When at rest less water will be required, and the plants placed in any house that does not fall below 50°. It flowers during late autumn.

**Cypripedium Schlimi.**—This little gem is hardly ever without a few flowers open, bloom-spikes being produced upon every growth. The flowers are too well known, perhaps, to need a detailed description, but they are always welcome on account of their soft and delicate colouring. *C. Schlimi* is a native of New Grenada, and was discovered at a great elevation by the collector whose name it bears about thirty years ago. It is said to be found on the banks of streams and other very moist and swampy places, where it is impossible for the roots to be dry for any length of time, and that it delights in this ample moisture at the root is proved by its thriving only under these conditions in our Orchid houses. The best compost for it is equal parts of peat fibre, loam, and Sphagnum Moss, with plenty of small crocks, and in potting, the surface of this should be kept below the rim, as in ordinary potting. Plants that are out of condition from any cause should have the flower-spikes removed as they appear, and if in a bad state, all the roots must be shaken clear of the compost and well washed in tepid soft water before being again repotted. It thrives best in a shady corner of the coolest house when well established, but newly-imported plants require more heat.

**Miltonia Moreliana purpurea.**—Under this name I have seen a very deeply coloured and large form of this most desirable species, the flower measuring over 3 inches across, and of a deep purple with lighter veins. This is one of the most useful of Orchids at this season, well-flowered plants making a very fine display and lasting a long time in beauty, almost rivalling the *Cypripediums* in this respect. Though strictly speaking a variety only of *M. spectabilis*, this is amply distinct as a garden Orchid.

### CATLEYA DOLOSA.

THE distinct appearance of this pretty Cattleya should ensure for it a greater share of popularity than it obtains at present. Were there a demand for it, plants would probably be forthcoming. I remember some few years ago assisting in blocking a number of plants of this species that were newly imported, and although these plants rooted and grew well, there was never the size of pseudo-bulb or of flower that I have since seen on plants grown in pots in the usual way. Block treatment, though apparently a natural mode of culture, is too poor for Cattleyas, though with the species in question, pieces of Tree Fern stem as advised by a correspondent in *THE GARDEN* recently for *C. superba* would probably make a very suitable medium. This is not, however, always obtainable, and the pot or basket has to be fallen back upon. These should not be large enough to hold a great body of compost, as the roots, though freely produced, are not very robust. Good peat with all earthy and sandy particles beaten out and nice fresh Sphagnum should be mixed in equal proportions and the plants placed in position. The crocks for the drainage may be brought neatly to the rim, covering the bases of some of the old back pseudo-bulbs if need be and raising in the centre to a convex pile. If the plants are newly imported this will suffice for the first season, but established plants will need a thin layer of the mixture mentioned above, working it in carefully about the roots with the dibber and pressing it moderately firm. Trim off all ragged ends neatly

and return the plants to the house. *C. dolosa* is an autumn-blooming species flowering on the apex of the newly-made pseudo-bulbs, and therefore it requires to be started in spring and grown in a good light all the summer in order to produce a well consolidated and ripened growth. After flowering, no difficulty will be found in keeping

yellow ground colour, this being overlaid with dark purple stripes, the colour fading towards the margin. The petals are very long, somewhat narrow, yellow, with wavy edges. These are thickly spotted over their entire length and have several dark lines running through them. The pouch is light brown, with shading of orange-red

much longer and prettily waved, of a glossy rich purplish rose, ornamented on the upper edges with short black hairs and having deeper longitudinal lines. The pouch is similar in colour to the petals, while in shape it is rather more pointed than *C. insigne*. It is a very pretty flower, and by the appearance of the scape it should be a healthy and a vigorous grower.

*Edraianthus Pumilio.*

the plants at rest during the winter, at which season only enough water to keep the pseudo-bulbs from shrivelling must be given. The flowers, each about  $4\frac{1}{2}$  inches across, are produced either singly or in pairs. The colour varies a little, more especially on the lip. The petals and sepals are usually of a soft magenta or rosy lilac, the lip rather lighter with a white and yellow throat and a broad marginal band of purple in front. In shape the flowers resemble those of *C. Walkeriana*, but the segments are fuller and more reflexed. *C. dolosa* is found in various parts of South America, and was first discovered in Minas Geraes, whence it was sent to this country in 1872. H.

**Cattleya gigas Sanderiana.**—I was rather surprised to see this exhibited at a Chrysanthemum show last week, as it usually flowers rather later than the type. The blossoms are large, of a pretty lilac-rose tint, and the lip is very deeply coloured, with a large blotch of orange-yellow in the throat. It is one of the very best forms of this popular species.—R.

**Maxillaria picta.**—This quaint old species is now in flower and is remarkable, not on account of the individual beauty of the flowers, but for the number produced from a single pseudo-bulb. On account of the incurved sepals and petals the flowers individually only measure about  $1\frac{1}{2}$  inches across. They are orange-yellow with many purple and brown spots. This species thrives well in pots in a mixture consisting of equal parts of peat fibre, loam, and chopped Sphagnum, and seldom gets out of health if kept in a shady, moist corner of the Odontoglossum house. As mentioned above, it is an old species, having been introduced as far back as 1832 from the Organ Mountains, in Brazil.

**Cypripedium Rothschildianum.**—This is a magnificent and very showy species, apparently of the same class as the remarkable *C. Stonei*. The growth is very vigorous, the leaves being each upwards of 2 feet in length, broad and deep green. The blossoms, each about 8 inches across, are produced on erect scapes, about two or three on each. The dorsal sepal is large and of a dull

about the opening. *C. Rothschildianum* requires plenty of heat and moisture to the roots, thriving well in a shady position on the stage in the East India house. Like all of this section, it shows a disposition to damping at the base of the leaves when newly imported, but when established grows freely and well. The ordinary compost as advised for *Cypripediums* suits it well, and the cultural routine will be similar. It is a native of New Guinea, and is quite an acquisition to this fine genus. It was introduced in 1888.

#### Three useful *Cypripediums*.

—Undoubtedly three of the most useful *Cypripediums* flowering at this season of the year are *insigne*, *Harrisi*, and *Spicerianum*. These were all exhibited in fine form at the Lincoln show by Mr. Wipf, of Hartsholm Hall. Their value is greatly enhanced by their succeeding in a comparatively low temperature, and by the fact that they will stand removal to the drawing-room or entrance hall without suffering, provided they are not allowed to remain there too long and are supplied with a moderate quantity of water only. The foliage of *Spicerianum* is very much like that of the old *insigne*, and very small plants rapidly increase in size, it being a very free grower. It is astonishing how many types there are of *Cypripedium insigne*, and I am of opinion that different soils influence the markings and shades of the blooms very much. I find *insigne* responds quickly when growing to moderate doses of liquid manure.—J. C.

#### *Cypripedium Tryanowskyana*.

—From Mr. Hugh J. Hunter comes a flower of this hybrid. It is as large as a good *C. insigne*, which in shape and in the colour of the dorsal sepal it somewhat resembles. The petals are, however,

## FLOWER GARDEN.

### EDRAIANTHUS.

It is difficult to understand why to so small and so distinct a genus as the *Edraianthus* should be given so many different names. The genus contains some half dozen varieties that are most excellent rock plants, and there can be no doubt that these are allied to *Campanula* and to *Wahlenbergia*. But as most *Campanulas* and *Wahlenbergias* are so entirely different in appearance to these species of *Edraiantbus*, why not retain De Candolle's good old name of *Edraianthus*?

The best varieties for the rock garden are *Edraianthus dalmaticus*, *E. graminifolius*, *E. dinaricus*, *E. Kitaibeli*, *E. Pumilio*, and *E. serpyllifolius*. All these are very pretty rock plants, which have been most successfully cultivated in many gardens, especially within recent years, but their names have been sadly neglected, and there is not a plant amongst the varieties mentioned which is not also known under quite a number of other names. Here is an example: *Edraianthus dalmaticus* (A. de C.), *Edraianthus caricinus* (Schott.), *Wahlenbergia dalmatica*, *Edraianthus caudatus* (Reichenbach), *Edraianthus tenuifolius*, *Wahlenbergia tenuifolia*. Just fancy half a dozen names for one

*Edraianthus graminifolius* and *E. dalmaticus* in the rock garden at Abbotsbury, Newton Abbot. Engraved for THE GARDEN from a photograph sent by Mr. F. W. Meyer.

plant! A judicious thinning-out of the names is surely very desirable, and the sweeping away of the useless synonyms would be hailed as a boon and a blessing by gardeners and amateurs

alike. But every one of these names is used in various catalogues of hardy plants, and I am not at all certain whether two more should not be added to the list, viz., *Edraianthus graminifolius* and *Wahlenbergia graminifolia*. I presume De Candolle must have found sufficient distinction from a botanist's point of view to justify the retention of different names for *Edraianthus dalmaticus* and *Edraianthus graminifolius*, but there is practically no difference between the two, or, if a difference exists, it is so trifling as to be invisible as far as flowers and foliage are concerned. Possibly there may be a difference in the seed which has escaped my notice. The accompanying engraving, fig. 1 (group of *Edraianthus dalmaticus* and *E. graminifolius*), will further illustrate the similarity of these "two" varieties. The group represented in the engraving was planted by me about two years ago in a large rock garden at Newton Abbot, and consists of five plants, two of them being *Edraianthus dalmaticus* and the other three *Edraianthus graminifolius*; to tell one from the other except by the label is impossible.

Having been very successful with *Edraianthus*, I will briefly state my experience in cultivating them. My remarks on this subject refer to the various species collectively as a genus, and not to any individual variety. According to my experience none of the varieties succeed well if planted on flat, more or less level ground, but if planted into an upright or abruptly sloping fissure, with the roots in a horizontal, instead of a vertical, position, success is certain, provided the work is properly carried out and the plants receive an abundance of sunshine. There are of course fast-growing and slow-growing varieties, but, with the exception of planting the dwarfest kinds closer together, I make no difference in the treatment. As the plants in the little group here illustrated (fig. 1) are in the most flourishing condition, a short account of the manner in which they were planted may prove useful to others.

The rock, which is facing south-east, was composed of pieces of limestone so arranged as to leave between them long, almost perpendicular, crevices 2 inches or 3 inches wide, and from 2 feet to 2½ feet in depth. These crevices were filled with plenty of broken stones for drainage, and before filling in the soil the lowest visible or outward part of a crevice was closed up by a small wedge-shaped stone, held in place by a kind of mortar made of clay and Sphagnum Moss, mixed with a very small quantity of soil. The small stones, acting as drainage, would be of course on a lower level and in the invisible or inside part of the crevice. By means of more "mortar" and more small stones the outside part of the fissure is now built up to the height where it is desired the first plant should be, and simultaneously the inside part of the crevice is filled to the same height with a mixture of loam, leaf-mould, small broken stones (limestone) and stony grit. The plant is then inserted with its roots in a horizontal position as mentioned before, and more of the stony soil is filled in and rammed around and between the roots with a small stick. On each side of the neck of the plant a small stone is next driven into the crevice in such a manner as not in any way to injure the roots, but to take the pressure of other small stones used for building up the front of the crevice above the first plant, say to the height of 10 inches or a foot in precisely the same way as was done below the first plant; the second plant is then introduced, and in the same way a third or fourth plant may be added according to the height of the fissure or the size of the plants,

but care must be taken not to use the clay mixture as mortar above the last plant, as the more or less impervious clay would check the free access of water to the roots. I use soil and Moss only as a "mortar" for small stones above the last plant. If the tiny crevices between the small stones are not filled up they become a harbour for slugs and other pests.

*Edraianthus*, or any other plants requiring to be grown sideways (*i.e.*, with their roots in a horizontal position), succeed remarkably well if planted in the manner just described, as water can never rest on the foliage of the plants to any dangerous extent, while free access of water and perfect drainage are assured to the roots. The native home of most *Edraianthus* is in South-eastern Europe and Asia Minor.

I will now give short descriptions of the varieties I have recommended.

*EDRAIANTHUS DALMATICUS* (A. de C.)—Five other names for this plant have already been mentioned, and I need, therefore, not repeat them here. This is one of the best of the genus; it is very robust in growth (as seen by the illustration, fig. 1), and perhaps the easiest to cultivate. In planting, the plants should be kept at least a foot apart, as their spreading tufts when in bloom cover a circle of quite a foot in diameter. The large flowers form clusters or heads, each consisting of from eight to twelve flowers, similar to those of *Campanula glomerata dahurica*, but of a still brighter violet-blue, and white at the base. May and June are the months of flowering. The leaves, which are linear and form dense tufts, are very numerous and of grass-like appearance. At a first glance their margins appear very minutely serrated, but on closer observation it will be found that they are entire, and that the apparent serration is due to very short stiff hairs, which evenly cover the margin throughout the entire length of the leaf, which is about 4 inches. The colour of the leaves and also of the very numerous bracts is a deep dark green. The height of the plant is seldom more than 4 inches or 5 inches, as the stout flower-stems do not stand up erect, but lie on the ground or stones. Dalmatia is said to be the native home of this charming rock plant.

*E. GRAMINIFOLIUS* (A. de C.) (see illustration, fig. 1).—If this is not identical with the former, it so closely resembles it in every respect that further description is needless.

*E. DINARICUS* (Kern.)—syn., *E. pumiliorum* (Vis.).—Of this variety an excellent coloured plate appeared in *THE GARDEN* of January 28, 1893, under the name of *Wahlenbergia pumiliorum*. It is one of the smallest of the genus and much more neat and compact than the robust *E. dalmaticus*; it should therefore be planted closer together if several plants are used to form a group. The flowers are nearly as large as those of *E. dalmaticus*, but they are of a more purplish shade of colour, more bell-shaped in form, and instead of being produced in large clusters, they appear either singly or two or three on a stem. The leaves are very small and narrow, each being 1 inch or 2 inches in length and about one-sixteenth to one-eighth of an inch in width, covered with very minute hairs on the upper surface. May and June.

*E. PUMILIO* (A. de C.) is still more compact than the former (see illustration fig. 2). The flowers are solitary and comparatively large, being quite 1 inch in length and about three-quarters of an inch in diameter, of a very bright and showy purplish blue. The upper surface of the leaves is covered with minute hairs to such an extent as to have quite a silvery appearance, which in all plants, as a general rule, is a sure indication of the requirement of a sunny position. But though the plant itself grows best when its foliage is moderately dry, its roots, though well drained, should never want for moisture. A very handsome specimen, which I had planted in the manner above described in Messrs. Veitch's nursery at Exeter, did remarkably well for several years, but

succumbed to drought during an exceptionally dry summer.

*E. KITABELI* (A. de C.)—syn., *E. croaticus* (Kern.)—grows much more robust than the former; it is a native of Bosnia and grows about 6 inches high. The flowers are large, purplish blue, and the leaves are slightly dentate.

*E. SERPYLLIFOLIUS* (A. de C.)—syn., *Campanula serpyllifolia* = *Edraianthus thymifolius* (Vis.).—This is a charming gem for the rock garden, and planted sideways into an upright or abruptly sloping fissure as mentioned above does remarkably well. The drought during last summer injured several plants under my observation, but they soon recovered. The flowers are very much like those of *E. Pumilio*, but perhaps of a deeper bluish shade. The foliage, as the name implies, resembles that of the Thyme, but is more compact and glossy. F. W. MEYER.

*Exeter.*

#### IS LAYERING BENEFICIAL TO CARNATIONS?

I NOTICE frequently with plants that are layered and transplanted they often are diseased, while others of the same sort that have not been layered or interfered with in any way show no disease and flower abundantly. I do not say the layering actually weakens, but I maintain that layering and transplanting combined are certainly not beneficial to the plants, nor do they provide us even with larger or better flowers or even in greater numbers. Take, for example, a few well-known border kinds, such as the old crimson Clove, Germania, or Raby Castle. Of the first I know of some large patches several feet across that have been left to themselves for at least three or four years. During this time they have not been layered or interfered with at all, and yet year by year these patches flower far more abundantly than those layered each year, that is to say, a much greater number of blooms may be taken from a bed 4 feet across. In at least four instances the plants are growing in the gardens of cottagers; in two the soil is of a clayey nature, these being in Gloucestershire, the remaining two in Middlesex and on light soil. The growth in each case is similar, *i.e.*, short and compact, and what strikes one is the perfect freedom from the disease to which this kind is so often subject, and which in some districts prevents it being grown at all. In one of the instances cited above I layered some of the growths late in the past summer, as I did in the same garden three years ago, and was informed they had not been touched in the interval. As is natural with retentive clay soil, the soil around these Carnations was quite hard and solid, yet the answer to an inquiry was that "we have had a splendid lot of flowers this year again." I layered a few of the longest, and specially requested the owner not to transplant them, as it seemed impossible to improve on such healthy, sturdy, vigorous patches.

I believe there is something beneficial in the solidity of the soil, that brings with it a certain restricted luxuriance that can scarcely be secured where the plants are layered and transplanted every year. I know that in the loose soil of Middlesex the old Clove dies if layered and transplanted; and yet in two instances about five minutes off, the same plant grows to perfection, with perhaps a couple of hundred growths in the one and quite close together. In the second the quantity is not so great, but in each I look in vain for any sign of disease. Then if we take Germania, another true border kind, we get fine stemmed flowers of nearly double the size when the plants are grown on a second year without layering. Those who only know Germania from the yearling layer have yet to see this grand yellow in perfection. I have experience of the tree varieties being very similar in point of size, and I often wonder whether it is age alone that makes all the difference; in these latter the plants were not shifted on at all. And so with those I refer to in the open garden; they were simply left alone. Or, if the whole thing turns on the age of

the plants and poorness and solidity of the rooting medium, it would be very easy of imitation, and I am inclined to regard it as so. At any rate, the private gardener need not add to his labour the annual task of layering and transplanting all his Carnations if it is bad for his plants, for even by layering and potting much loss and disappointment ensue. Let a few gardeners try a bed or two of a plentiful kind, and at planting time ram them very firmly into the soil. Avoid manure and dispense with layering, and note the results. E. J.

#### FLOWER GARDEN NOTES.

**HARDY PLANTS.**—Besides their employment on borders specially reserved for them and in the more outlying parts of the garden, as, for instance, in connection with shrubberies, many hardy plants have of late years been introduced into the formal garden with so much success, that the experiment might well be tried on an extensive scale, especially in those places where labour is somewhat scarce and insufficient to maintain a lot of summer-bedding plants at a high pitch of excellence, particularly in those seasons when these plants require constant attention in the way of watering to produce such results. I should like, however, to point out that in those cases where it is deemed advisable to utilise hardy plants for the geometrical garden, beds of such plants show to the best advantage on turf. Surroundings of Box and tiny gravel paths are not natural associations. Box and gravel should be removed, to be replaced by good bold beds cut out on the turf, allowing plenty of space between. The planting may be carried out to suit any special tastes—a mass of one variety in each bed, bold central blocks with a broad dwarfed edging, or nice large clumps of a fairly tall species, with a dwarfed plant worked in and around such clumps. A few such combinations that may be suggested in the last-named style would be Paeonies, Aquilegias or *Lobelia fulgens* with Pinks, Spiraeas and Pyrethrums with Violas or dwarf Veronicas, Japanese Anemones in the rose and white shades with Iceland Poppies and the like. In the case of species that are represented by a great number of varieties, as the Starworts, Phloxes, Campanulas, &c., large beds might with advantage be filled with one family in variety. If we have, for instance, round or oblong beds of considerable size, the centre might be partially filled with clumps of the taller Phloxes, the *suffruticosa* section planted in a similar manner nearly to the edge, and all the clumps relieved by a carpet of Phlox *subulata* in variety running throughout the bed. The wealth of material at the disposal of the planter in the Starworts and Campanulas should render the task of filling occasional beds with these a comparatively easy matter, whilst the difference in the flowering season between the several sorts would give a certain amount of colour in such beds for a very long season. It was partly the desirability of securing a protracted display that led to the suggestion of a combination of a dwarfed carpet with such things as Paeonies, Spiraeas, Aquilegias, &c., which, although very beautiful in their season, are somewhat quickly over. In the case of beds that lie at the extremity of lawns it will generally be found advisable to fill them with tall-growing plants, as the taller of the Starworts, perennial Sunflowers, and Solidagos, whilst to give a little

variety, room might be found for an occasional clump of Pampas Grass, of the hardy Bamboos, *Bocconia cordata*, *Rhus Cotinus*, or any other ornamental plant of similar size. If alterations of considerable extent are contemplated in the flower garden during the coming autumn and winter, and the plants are to hand, that is, if they are to be shifted from one place to another, the ground about them, and also the spaces to be occupied by new beds or borders, may be mulched with litter, Bracken, or rather long manure. The work of preparation may then continue irrespective of frost, and the lifting and replanting also, unless the weather is exceptionally severe.

**PRESENT WORK.**—Besides the alteration of some borders and planting up others, there is not much to chronicle in the way of flower garden work at present, except the gradual digging up of beds that are to remain empty through the winter, and mulching those herbaceous borders that are in a satisfactory condition and require no alteration.

Richard Gilbert.

A frosty morning is a good time for mulching. The workman should be instructed to break the material up well with his fork, so that it does not go on in lumps, and to avoid the use of leafy matter that would dry quickly and be scattered in all directions with the first high wind. The old stems that are cut away from the border Fuchsias and the stouter of the Starworts may be stacked in a shed, and will afford a job for the first wet day. If stripped, cut into lengths, and tied up in bunches they will answer well for laying in shoots at the summer training of wall trees. Any hardy plants that were sown in spring and shifted on into boxes may be transferred to permanent quarters with the clearing of the beds. The ground for their reception should be well broken to pieces, especially if the plants are small, and a surface mulching of cocoa fibre or leafy matter—partially decayed leaves, that is—is advisable for all things that might suffer from the attentions of slugs.

**PYRETHRUMS.**—A recent note on Pyrethrums suggested that spring instead of autumn planting was occasionally advisable, given certain conditions of soil, but I should be inclined to advise an alteration of those conditions rather than to defer the planting, the experience of the spring of 1895 being altogether against a waiting policy. The frost was not out of the ground until the middle of March and planting was not practicable until quite the end of that month. A spell of very dry weather followed, with the result that all stuff not well established made no headway, and was not seen to advantage at the time when it ought to have made a good show. If in connection with Pyrethrums a mass of colour on a large scale is deemed more advisable than a great variety of shades, three of the best sorts to plant are Aphrodite, Meteor and Celia, and, following up the idea of planting suggested earlier in these notes, three good Violas to associate with them would be J. B. Ridging, White Swan and Evelyn.

**BEGONIA DISEASE.**—Thanks are due to correspondents who have furnished us with the necessary remedial measures to cope with thrips on Begonias, but so far as I am personally concerned they are not of any value, the disease that affected my plants not being caused by thrips or anything in the way of insect life. I have received specimens of leaves attacked by the minute form of thrips and examined them closely, and the inference drawn therefrom was that the two visitations were totally distinct. In my case the spot went right through the leaf, and the part so affected, apparently all right this morning, would at night resemble a piece of tissue paper or even of less substance than this. From the description given in several notes, I should imagine that others have suffered in a like manner and that I have yet to find a remedy. *Begonia Worthiana* was very badly attacked outdoors during one of the wettest summers of the century, a summer when drought-loving insects like red spider and thrips were conspicuous by their absence. Claremont. E. BURRELL.

**Lapagerias in the open.**—Lapagerias may be considered practically hardy in the south-west of England, and Mr. R. W. Nicholson's note (p. 369) shows that in North Wales in sheltered positions they are the same. I am acquainted with five cases where these beautiful climbers are growing out of doors. At Kingswear, on the banks of the Dart, both the red and white varieties were doing well a few years ago. This was, however, in an exceptionally favoured spot, entirely sheltered from the north and east winds—*Plumbago capensis* also growing in the open and flowering in the same garden. Fine plants of *L. alba* and *rosea* are now in flower against the north wall of the private chapel adjoining Gnaton Hall, near the river Yealm, S. Devon. They are planted in peat and have made vigorous growth, reaching the eaves of the building. The flowers are very large and handsome, those of *L. rosea* in particular being of far greater size and more brilliant in colour than blooms grown under the shelter of glass. I find that in no winter since their planting have these plants been afforded the slightest artificial protection, yet the severe weather at the commencement of the present year has had no deleterious effects on them, as they are now in the best of health. Many specimens of *Escallonia macrantha* have, however, been killed during the winter, and this shrub is evidently much less hardy than is generally sup-

posed. Given a deep bed of peat and sand, with good drainage and an ample supply of water during the growing period, no one need despair of growing the *Lapagerias* successfully as climbers in the southern counties. Care should be taken to prevent the slugs eating off the young shoots, of which they are inordinately fond.—S. W. F.

## OBITUARY.

### RICHARD GILBERT, OF BURGHLEY GARDENS.\*

A GOOD man and a good gardener has passed away to a well-earned rest, and some of those—and they are many—who best knew his life and his ways will feel that men may come and men may go, but that they are not likely to look upon his like again. To many, Mr. Gilbert's death on the 22nd inst., in his seventy-fifth year, will come as a surprise, but he had been ailing for some time, and a more than usually severe bronchial attack carried him off on the date named. In August last I had the pleasure of spending a happy day with him in the well-known High Park Gardens at Burghley, and found him seemingly hale and hearty as of yore, though even then he had symptoms that gave his family and personal friends some uneasiness, but his own character was ever the reverse of a doleful or complaining one, and his well-known cheerful conversation full of keen observation as to both men and things. Amusing it always was, but a ring of strong common sense that ran through all he said always redeemed his remarks from aught that was commonplace, uninteresting or unkind. His subtle and exquisite sense of humour was one of his personal charms, but it was used delicately and served to cheer and vivify; for even his strictures had a manly sympathy of tone that endeared him to all with whom he came into contact during a useful and honoured career. He was courteous and genial to all, rich or poor, and all gardeners had his aid and sympathy in their troubles, as well as generous appreciation of their success. To young gardeners especially he was a kind and considerate employer, and no foreman or journeyman ever left Burghley except to take up a better position, in many, even if not in most cases secured for them by our worthy friend. To say that such a man was popular is not enough; he was sincerely respected and deeply beloved. Many successful gardeners to-day owe their position to Gilbert of Burghley, who forwarded their interests with a peculiarly quaint professional pride. Mr. Gilbert was, I believe, a native of Sussex; at any rate he always referred with pride and pleasure to his early experiences at Arundel Castle and at Worksop Manor under the late Mr. John Wilson, of Mr. Myatt, and of the pleasant days in the old Chiswick Garden of the R.H.S., when Dr. Lindley held command there, and the gardens had not been shorn of their area and prestige.

As a gardener, his strength lay in the superb cultivation of all sorts of fruits and vegetables. Flowers he loved, and could grow well also, but his real strength went to the fruit and kitchen garden. His own productions are now familiar to us all, and amongst many others I need only name Chou de Burghley, the Burghley Brussels Sprout, Tomatoes and the Universal Savoy. The Grapes, Figs and Melons at Burghley were specialities, but Gilbert was even more proud of his successes with his friend Laxton's new Peas, Potatoes, Tomatoes and Strawher-

\* Died at Burghley, November 22; buried at Barrack Churchyard, November 25, 1895.

ries, and he was especially proud of his triumphs in the way of open-air Peaches in a cold midland climate, apparently not at all suited to such a culture. His strain of beautiful double-flowered Chinese Primroses is well known, and was figured in *THE GARDEN*, vol. xvii., p. 176, and the Harbinger Primrose as grown at Burghley was an especial favourite with him. Mushrooms, both indoors and in open-air beds, were largely and well grown, and he had a knack of producing early Potatoes in January and February by selecting the sets in July or August and keeping them cool and dry for a year, after which they were planted in boxes of leaf-mould and placed in a warm, dark position, where they produced new tubers from the old sets without any haulm or top growth whatever (*vide THE GARDEN*, February 15, 1879, p. 150).

We may also refer to his practical and handsome way of growing pot Vines bearing ripe fruit for dinner-table decoration (*THE GARDEN*, vol. iv., Oct. 25, 1873, p. 333). Readers of *THE GARDEN* will remember the original and pithy manner in which our friend announced his new productions. One of these may be quoted as a specimen from this paper, March 29, 1890 (p. 307), where his friends are offered the choice of "Potatoes without disease, Peas without mildew, and Cabbage that requires no bacon." As an inventor, Mr. Gilbert years ago gave us improved handlights or portable plant protectors that are most useful in gardens, both large and small.

Mr. Gilbert had considerable literary ability, his contributions to *THE GARDEN* and other horticultural publications being remarkable for their short and pithy sentences and for their sterling common sense. The following note from Mr. Gilbert reveals a good deal of the man. It is from *THE GARDEN*, vol. xxxi., March 25, 1887, p. 222:—

I am waiting to show round the Earl and Countess of Rosslyn, and I cannot employ my time better than in giving you a bit of my mind. In the first place you tell the public I should raise seedling Apples and get varieties to match the American. You certainly do not say as much, but I read between the lines that you mean as much. Let me tell you I have been raising Apples for twenty years, but, unfortunately, have not yet got a good one. At the great Chiswick Apple show I picked out two varieties out of 8000 dishes which I thought the best, ordered the trees (eight) at 7s. 6d. each, but they were reported as sold! I write to let you see I am preaching progress. I will send you a dozen seedlings by post. Now I hope in the next edition of *THE GARDEN* that you will put me on my merits. Do not let it be said that I raise Cabbages alone! If you could see my houseful of Harbinger Primrose, you would say and think differently. Next week I am going in for Peaches outside, that nobody appears to grow. Depend upon it, this is a matter of over-building Peach houses, exactly the same as in the case of Melons. Nobody can grow Melons now in manure frames, because they have houses!

[An interesting and suggestive note, as most of Mr. Gilbert's are. We are glad to hear of all his doings. Peaches out of doors and Melons in frames are, we hope, not to disappear from our gardens, of which they were once the pride. The last time we were at Burghley we saw good Peaches on walls there. The place is not nearly so favourable for that fruit as many districts in the south and west of England.—Ed.]

As superintendent of the extensive gardens at Burghley House for nearly thirty years Mr. Gilbert met the most distinguished people of all ranks, and the late Marquis of Exeter not only valued him as a good gardener, but treated him as a faithful friend, and left him a substantial legacy upon his death some few

months ago. By his fellow-gardeners Gilbert has for many years been recognised as a master of garden craft, and he leaves behind him a memory that will ever be green to all who enjoyed his genial friendship. He leaves a widow and a family of grown-up children to mourn his loss. A most lovable man has left the world richer than he found it, for his presence ennobled life, and he will long be missed from the locality he had made in a sense his own. Of sturdy build and full of energy, Gilbert always reminded one of the Oaks of his native county, not particularly large in size, but strong-hearted and sound to the core.

F. W. BURIDGE.

**Mrs. Bruce Findlay.**—We regret to announce the death of Mrs. Bruce Findlay, which took place at the Botanic Gardens, Manchester, on Wednesday, November 20.

**Mr. James Walters.**—We regret to announce the death of Mr. James Walters, of the Mount Radford Nurseries, Exeter, which occurred on the 20th inst. Mr. Walters was widely known, and his loss will be felt by many friends.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 26.

THERE was an appreciable falling off in the number of exhibits at this meeting, yet there were quantities of most interesting things staged for the inspection of each committee. The falling off was in the miscellaneous groups, &c., usually to be seen at these gatherings, leaving the chief points of interest to be centred in the newer or more uncommon plants. There was an excellent attendance, taking into consideration the busy season of planting now in full swing.

The floral committee had no finer exhibit placed before them than the group of hybrid *Rhododendrons* of the javanic-jasminiflorum hybrids of Veitchian origin. If anyone should previously have had doubts as to the decorative value of these charming flowers, such doubts should, after an inspection of this exhibit, be entirely dispelled. These choice hybrids will always remain one of the greatest triumphs of the hybridiser. In the exhibition in question there was a wide range of colour, whilst the whole of the plants were flowering in a small, and in several instances in quite a dwarf stage. *Chrysanthemums* constituted the next important feature here, several very promising novelties being staged by the best-known growers.

The Orchids were not numerous. Several good and choice things chiefly in hybrids were, however, staged; these consisted chiefly of *Cypripediums* and *Calanthes*, whilst of species the most notable was the new *Catasetum imperiale* from M. Linden, this being the only Orchid shown to which a first-class certificate was awarded.

Before the fruit committee the two chief exhibits were the collection of vegetables, chiefly of the Brassica family, of which some forty vars. were staged with other good vegetables in season from Syon House by Mr. G. Wythez, and the comprehensive exhibit of Apples and Pears by Messrs. J. Cheal and Sons, Crawley, most prominent amongst which were the grand fruits of Bismarck Apple, both size and colour being most noticeable.

#### Orchid Committee.

A first-class certificate was awarded to—

**CATASETUM IMPERIALE.**—A very distinct and noble-looking species, of which one plant with a spike of eight blooms was shown. The flowers are individually above the average size, the labellum, as usual, being the most prominent feature; this is large and of wax-like substance, incurved in shape, the pervading colour being a

deep claret tint with a greenish white edge, broader towards the front part; the upper sepal is slightly tinted also with the same colour, whilst the petals are creamy white, the growth robust. From Mons. Linden, Brussels.

Awards of merit were voted to the following:—

**CATLEYA AUREA VAR. MARANTINA**, which, as usual, has a splendidly developed lip, with the purplish crimson of a darker tint than usual and pervading the same to its base, the golden veining being less prominent than usual, with pencilings here and there of the purplish crimson in the petals and slight flushings in the sepals even. From Mr. T. Statter, Stand Hall, Manchester.

**EPIDENDRUM WALLISI-CILIOLARE** (E. Wallisi × E. ciliolare).—A very distinct hybrid, having more of the style of growth of E. Wallisi, but with increased vigour and sturdier habit, E. ciliolare being in the way of a Cattleya in growth. The flowers partake more of the former parent, being slightly larger and paler in colouring; the sepals and petals are self-coloured (a bronzy buff), the spots of E. Wallisi being quite eliminated; the lip is of a pale straw colour and fringed, but not so much as in E. ciliolare. From Messrs. J. Veitch and Sons.

**MASDEVALLIA CHIMERA AUREA**.—A distinct form of this well-known species, in which the chief distinctive feature is the old gold ground colour, overlaid with the veining and network in a dark tint of maroon. The flowers being drooping, they did not show to advantage. From the Botanic Gardens, Glasnevin.

**CYPRIPEDIUM PLATYCOLOR** (C. concolor × C. Stonei platytanum).—A hybrid which attracted much attention by reason of the almost total disappearance of any influence of the last-named parent, the only perceptible trace being in the elongated lip. The one spike bore three fresh, well-developed flowers, the ground colour of which is a creamy yellow, suffused and spotted with vinous purple, both the dorsal sepal and the petals pointing clearly to C. concolor, whilst the foliage had some trace of C. Lawrenceanum, only in a less marked degree. From Sir Trevor Lawrence's collection.

**CYPRIPEDIUM MADELEINE** (C. bellatulum × C. Argus).—In which again the influence of the former parent greatly predominated, the petals here showing traces of C. Argus in the spotting, whilst the contour of the flower was decidedly towards C. bellatulum, the creamy ground colour being profusely spotted and flushed with a dark claret tint.

Botanical certificates were awarded to Arundina Philippi, a very pretty Orchid, of slender, Grass-like growth, surmounted with small flowers of Phaius-like form, the sepals and petals white, with a flush of purple, and the lip well marked in the same tint; from Sir Trevor Lawrence; Dendrobium subclausum, from Mollucas, a species of very slender growth, studded here and there with small orange-scarlet flowers; from Messrs. J. Veitch and Sons; Calanthe sp., new, with small, dark rosy purple flowers, and the stems of a dark bronzy green. From the Botanic Gardens, Glasnevin.

To Messrs. Sander and Co. was awarded a silver Banksian medal for a select group, which consisted of several of the best of more recently raised hybrid Calanthes, as C. Bryan, somewhat in the way of C. vestita rosea, the colouring being a deep vinous red; C. Wm. Murray, also with white sepals and petals, the lip entirely suffused with similar colouring to the last; C. Bella, with its flowers entirely suffused with rose colour; C. Florence, another beautifully tinted variety, and C. Clive, of a deep rosy shade, in the way of C. Veitchi. Cypridium consisted of C. Ashburtoni expansion; C. Mme. Cappe, a distinct looking hybrid; C. Alcides, a hybrid between C. insigne album marginatum and C. hirsutissimum, the latter parent being distinctly noticeable in the petals, and C. maculatum, a massive looking variety. Of Odontoglossums there was an excellent form of O. crispum of great purity; O. biconvexum

album was also shown. Other good things comprised a splendid mass, full of flower, of Sophronitis grandiflora and a brassia plant of a finer variety of this species; Brassia Lewisii, with less of the greenish tints and more yellow than in most species; Phaius-Calanthe Berryana, a cross between Phaius Humbloti and Calanthe masuca, with traces of each of its parents very distinct; P.-C. Arnoldæ, an improving hybrid; Angræcum polystachys, a charming small-flowered species of erect growth; Habenaria Susanne (again included), Bulbophyllum crassipes, a singular Orchid with short dense spikes of dark flowers; Lycaste Skinneri in two distinct forms; Bollea Schrederiana, certificated last year; Odontoglossum Schrederianum, a distinct species and very pretty; Pescatorea Lehmanni and P. Klaboehorum, Laelia autumnalis alba of the purest white, and Aganisia ionoptera.

Mr. Lucas, Warnham Court, Horsham, showed Cypridium warnhamense (C. Curtisii × C. philippinense), a distinctly beautiful hybrid, with long drooping petals, these being spotted with vinous purple on a pale straw colour ground, the pouch being of a bronzy tint, and the ivory white dorsal sepal lined with dark purple. From Mr. G. H. Palmer, Springfield, Trowbridge, came a few good hybrid Slippers, C. St. Mark being much after C. Lathamianum, with a bold flower; C. hyb., with a large lustrous, dark-coloured flower, and another after C. Leeanum, with others in a cut state. From Sir F. Wigan came varieties of Barkeria spectabilis, including the best forms. From the same source came Laelia-Cattleya Ingrami, a superb dwarf hybrid between C. aurea and Laelia Dayana, the influence of the former parent being very perceptible in the rich velvety crimson and wavy margin of the lip, the sepals and petals taking more after C. Dayana.

From the Botanic Gardens, Glasnevin, came Phaius Bernaysi (Fiji), a lovely species, with soft lemon-yellow sepals and petals, the reverse side ivory-white, and the lip a pale golden yellow. From the Marchioness of Londonderry, Wynyard Park, came a good variety of Laelia anceps, and from Mr. Temple, Leyswood, Groombridge, Cattleya labiata (Temple's var.) with large, but pale flowers, and Cattleya Miss Williams (C. Harrisoni × C. Gaskelliana), in the sepals and petals of which there was a clear lilac tint, dus no doubt to one of the best forms of its former parent. Mr. Statter showed Cypridium plumosum (?), a very dark looking hybrid, the dorsal sepal affording a relief in its margin of white. C. Leeanum giganteum came also from this source. From Messrs. E. Vervaeet and Co., Belgium, came a cut example of Odontoglossum crispum Franz Masurel, with bright crimson spots in the sepals and petals; it is one of the most intensely coloured forms. Mons. Linden showed Cattleya maxima, a good form, but damaged in transit. Messrs. Hugh Low and Co. showed hybrids and species of Cypridium, amongst which were C. Lecanum grandiflorum and C. L. superbum, two of the best forms; C. Harrisoni superbum, C. Niobe, a lovely little hybrid, and C. callosum grandiflorum, with the dorsal sepal of an unusual size. Phalaenopsis intermedia Portei and Cattleya aurea were also included, the latter a fine bloom. Cattleya Triana, an extra good form with large well-marked lip, came from Mr. Clark, Wrexham, the flowers being evidently from an imported plant.

#### Floral Committee.

Awards of merit were granted to the following:

**BEGONIA FROEBELI INCOMPARABILIS**.—This fine winter-flowering Begonia is the result of crossing B. Froebeli and B. polypetala, the characteristics of the former parent being most prominent. The plant has enormous leaves shaped like those of B. Rex, the full-grown ones being 18 inches long and 13 inches wide. They are of a deep green colour with the leaf veins somewhat depressed, giving the surface a wrinkled appearance. These great leaves droop over and hide the pot. In leafage alone the plant is remarkably striking, but even more so in bloom. The flower-stems rising to a

height of nearly 2 feet, stand up boldly erect, the flowers disposed in a branched raceme, from 20 to 30 buds and blooms being counted at the top of one of the several spikes the plant was carrying. The flowers, each about 1½ inches in diameter, are of a rich glowing red colour and brilliantly effective at this dull period. It was shown by Mr. J. T. Bennett-Poë, Holmwood, Chesbunt.

**ROSE ENCHANTRESS**.—This is a new Tea-scented variety and possesses the free and persistent flowering merits of this race, as was abundantly shown in the large group of plants shown. The flowers in the bud and half-expanded state are slightly blush-tinted, but with age they turn to a soft, pale cream colour, and in this state much resemble those of the variety Mme. Hoste. The form is globular, the flowers droop, and scent is but faintly perceptible. The number of plants shown and the many flowers they carried point to its usefulness as a forcing kind, and doubtless another summer we shall be able to form a better opinion of its merits from open-air blooms. It was raised and shown by Messrs. W. Paul and Son, Waltham Cross, Herts.

**CHRYSANTHEMUM GOLDEN DART**.—A Japanese variety, likely to prove useful to market growers or anyone requiring cut flowers in quantity. It is of the W. H. Lincoln type, of a rich yellow colour, and carries its flowers upon a good length of stem, whilst the habit of the plant is another point in its favour, as its height does not exceed 4 feet. Its raiser worked to secure a plant that could be housed in the low-pitched structures so much used by market growers, and he has realised his aim as far as this kind is concerned, which should become a popular market sort. It was raised and shown by Mr. E. H. Jenkins, Hampton Hill.

**CHRYSANTHEMUM BONNIE DUNDEE**.—This is an incurved kind, the florets rich bronzy buff, flushed with yellow towards the edge, their inner surface pure yellow. The flowers are of medium size. It came from Mr. R. Owen, Maidenhead.

**CHRYSANTHEMUM COUNTRY OF GOLD**.—This belongs to the decorative class, and has small tasselled flowers borne freely in graceful sprays and of a clear yellow colour. Also from Mr. Ower.

**CHRYSANTHEMUM MRS. ELLEN NEWBALD**.—Another decorative variety bearing lovely clusters of flowers of a soft canary yellow colour and reflexed form. This also was shown by Mr. Ower.

**CHRYSANTHEMUM OLIVE OCLEE**.—This is an incurved Japanese, extra broad in petal, the flower full, deep and well finished. The outer petals are bronzy yellow, but those towards the centre are pure yellow. It was shown by Mr. H. J. Jones, Lewisham.

**CHRYSANTHEMUM SURPRISE**.—An Anemone-flowered variety with large shapely blooms, in colour deep lilac suffused with white, the outer petals spreading, but prettily incurved at their tips. Also from Mr. Jones.

**CHRYSANTHEMUM WILLIAM SLOGROVE**.—This is an incurved Japanese of a deep rich yellow hue and great size, but there is no refinement in such mop-like blooms. It came from Mr. W. Slogrove, Gatton Gardens, Reigate.

There were not many miscellaneous exhibits on this occasion. Messrs. J. Veitch and Sons received a silver Banksian medal for a very attractive group of the Javanese Rhododendrons, many varieties being shown in a wide range of colour from pure white to deepest red. A similar award was granted to Messrs. W. Paul and Son for their fine exhibit of pot plants of the Tea Rose Enchantress, already described, more than a dozen well-flowered plants, making a prominent group. Mr. R. Owen also received a silver Banksian medal for an exhibit comprising a number of new Chrysanthemums, noteworthy varieties being W. Owen, dull chestnut-red; Princess Maud, blush; Mme. Lebeque, white; and Major Bonaffon, the new incurved yellow. Mr. H. J. Jones showed some fine kinds, as Mrs. J. H. Harvin, white incurved Japanese; Snowstorm, a long-petalled single white kind; Doree nona, pretty blush, reflexed; and Major Bonaffon, in very fine form. Mr. W. Wells, Redhill, showed several

Japanese and incurved kinds. Mr. Herrin, Dropmore Gardens, sent bunches of an old thread-petalled decorative kind named Gold Thread, in colour a harmony of red and gold. Mr. H. Briscoe-Ironside also had a varied selection of kinds of his own raising, whilst Mr. W. Jinks, Weybridge, and Mr. M. Silsbury, Shanklin, Isle of Wight, also contributed several kinds. *Dracaena lentiginosa*, shown by Messrs. J. Laing and Sons, is like the narrow-leaved *Cordyline* in all respects save colour, its leaves being a dark bronzy green. From Mr. Crawford, Coddington Hall Gardens, Newark-on-Trent, came three bunches of winter-flowering Carnations; and Mr. F. W. Moore, Botanic Gardens, Glasnevin, sent a cluster of flowers of *Sphaeralcea umbellata*, a malvaceous plant having dull red flowers. *Canarina campanulata*, a curious climbing plant with large bell flowers quaintly coloured in terra-cotta and chocolate, was shown by Mr. Rapley, gardener to Mr. H. Grinling, Harrow Weald; and from Mr. J. Crook, Forde Abbey Gardens, Chard, came a bunch of the well-known, always-blooming *Primula floribunda*.

#### Fruit Committee.

There was a limited number of exhibits before this committee, only two large collections being staged, one of fruit, the other of vegetables. Many seedling Apples were sent, but only one was considered worthy of an award.

An award of merit was given to—

APPLE STUBBS' SEEDLING, a medium-sized fruit. It is very highly coloured, somewhat like Devonshire Quarrenden in colour, but larger, flesh firm and of excellent flavour. It is a valuable addition to the dessert varieties and a good keeper. From Mr. W. Palmer, Andover.

Messrs. Cheal and Sons, Crawley, Sussex, sent a very fine exhibit of Apples and Pears, 100 dishes being staged. A large mound of very fine Bismarck Apple was specially noticeable. Jubilee and The Queen were also very fine, with grand examples of Alfriston, Waltham Abbey Seedling, Lane's Prince Albert, Peasgood's Nonsuch, Cox's Pomona, and other cooking varieties. Among dessert varieties, Margil, Armorer, Cox's Orange, and Ribston Pippin were noteworthy. Beurré Sterckmans, Chas. Cognac, Duchesse de Nemours, Beurré Abbé Lucas, Duchesse de Mouchy, Vicar of Winkfield, Josephine de Malines, and Bergamote Colette were the best Pears (silver Knightian medal). Mr. Wythes, Syon Gardens, sent three dozen varieties of Brassica, with Leeks, Asparagus, Seakale, Mushrooms, Cucumbers, and Endive. The collection was sent to show the green types of vegetables in season. Snow's Winter White, Walcheren, and Veitch's Protecting Broccoli were staged in quantity, a dozen varieties of Borecole, the Scotch Green-cured and Arctic Kales being very good. Several varieties of Savoys and Cabbage of the Colewort and St. John's Day varieties, Dwarf Gem, Paragon, and Paris Market Brussels Sprouts, and Sion House and Telegraph Cucumbers were also noteworthy (silver Knightian medal). The same exhibitor also sent a seedling Potato, Wythes's Seedling, a cross between Myatt's Ashleaf and Beauty of Hebron. This the committee requested to be sent to Chiswick for trial. A new Artichoke named Vilmorin's New White was also sent. It has a very nice tuber of superior shape, being much longer, with fewer knobby protuberances, and with a white skin. Mr. Farr, Spring Grove Gardens, Isleworth, sent his new Tomato All the Year Round. This was certificated this year. The fruits sent were of excellent quality, and the fruiting growths were heavily laden with well-coloured fruit, showing its value for winter cropping. A very nice dish of Tomato Nield's Seedling, somewhat like Conference, came from Mr. Nield, The Horticultural College, Cheshire. It was requested to be sent to Chiswick for trial next season. Mr. J. Crook, Forde Abbey Gardens, Chard, sent Coe's Late Red Plum, nice fruits, but past their best as regards flavour. Mr. Palmer sent a new seedling cooking Apple, a very late fruit. This was desired to be

sent again later. Mr. Wythes sent a seedling dessert Apple named Christmas Pearmain. Mr. Stewart, Nottingham, also sent a seedling Apple. Messrs. Lane and Son, Berkhamsted, had a very fine basket of Lane's Prince Albert, well meriting the cultural award given.

The lecture by Mr. J. Mason was on Asparagus. He briefly alluded to the plant's natural affinities, distribution in a wild state, and the reputed length of time it has been cultivated, which is believed to date back beyond the commencement of the Christian era. As a market grower of over thirty years' experience, it was his opinion that we were able to produce in England Asparagus which, though not so large in size or so taking to the eye, was superior in quality to that sent into our markets by the foreign growers. Large areas of land to the south-east of London that at one time were almost wholly devoted to Asparagus were now covered with houses, but he thought fresh land should be brought into a suitable state and devoted to this vegetable. In the preparation of the soil, sowing the seed, best age at which to transplant, and most suitable period of the year for doing it, he advised no change in or departure from the practice familiar to all practical men, which he briefly detailed. Deviation from the approved methods meant disaster as regards this vegetable, as, for example, in regard to planting he once when experimenting made a new plantation in the winter and lost ninety per cent. of the plants. He favoured culture in rows at 2½ feet apart with 1 foot between the plants, this way being preferable to beds, as it involved much less labour. There was a good attendance and the lecturer was heartily thanked for his able and very practical address.

### NOTES OF THE WEEK.

**Carnation Yule-tide.**—Mr. J. Forbes, of Hawick, sends us some blooms of a seedling Tree Carnation. The flowers, rich scarlet, are well formed, do not split the calyx, and the plant appears to be of a strong and vigorous growth. It has been awarded a first-class certificate by the Scottish Horticultural Society.

**Begonia Froebeli incomparabilis** shown at the last meeting of the R.H.S. was greatly admired. It is of noble growth, with large leaves, yet of dwarf habit and with tall erect spikes of vivid scarlet flowers of the true *B. Froebeli* form. This noble plant came from Mr. Bennett-Poë's collection of choice subjects.

**Chrysanthemum Phœbus.**—Mr. H. Shoemsmith, Claremont Nursery, Woking, has sent us a remarkably fine flower of this new Chrysanthemum, which has been largely shown this year. The flower is large, pure yellow, full and deep, and of exceptional substance. It ranks among the best of the new varieties, and will no doubt be often seen on the exhibition board. Included were some fine sprays of the useful single kind Purity.

**Campanula hederæfolia.**—A very pretty dwarf Campanula, found in mountainous and rocky districts in Europe and North America. It forms handsome tufts with slender, spreading branches, which recurve and creep along the ground, bearing angular leaves of a pale green colour and small, light blue solitary flowers on slender peduncles. This handsome trailing Bell-flower loves the full sunshine and a position on rockwork, but does not thrive in calcareous soil.—H. CORREYON.

**Androsace Charpentieri.**—A charming tufted plant, forming a cushion of verdure of a greyish green hue, and composed of numerous rosettes of elliptical, very obtuse and slightly pubescent leaves. In May and June it bears numerous flowers of a fine carmine-rose colour on flower-stalks about twice the length of the leaves. This is a rare species found on the Alps of Lom-

bardy, and easily acclimatised by sowing the seed. It requires full exposure to the sun and a well-drained crevice on a rockwork.—H. CORREYON.

**Angræcum Leonis.**—This is a native of the Comoro Islands, where it is said to have been collected at an altitude of 5000 feet. It is a singularly distinct Orchid, and even for an *Angræcum*, a very beautiful and interesting one. Its thick, flat leaves, like a scimitar in shape, are set edge-ways in two opposite rows, as in the Irids. It is a free flowering species, producing abundant racemes of two or more flowers. The *Angræcums* do not give us much variety in colour, and this, like all the others, is white, but of a purer shade than frequently happens. The flower is 2 inches to 3 inches wide, the lip being twice or thrice the size of the petals. It has a spur about 5 inches long, twisting upwards at about half its length, forming a loop about the middle. The species is also known as *A. Humbloti*, both this and the present name being given in honour of its discoverer, M. Leon Humblot. On the whole, there is perhaps no *Angræcum* so desirable as *A. sequipedale*, but after that *A. Leonis* is the one most people would wish to first possess.

**Cymbidium Masteri.**—There are few white Orchids flowering during the last two months of the year that are more attractive than this. It is most graceful in habit, having slender arching leaves 1½ feet to 2 feet long. The flowers, too, are borne very freely and are almost entirely pure white; there is, however, a patch of yellow on the throat of the lip, and it is also marked with a few spots of a rose-purple colour. Its value is enhanced by the Almond-like perfume of the flowers, which are usually from three to six on each spike, and individually measure from 2 inches to 3 inches across. The species is a native of Assam, and was introduced to this country in 1841. Like most of the *Cymbidiums*, it likes a compost which contains at least one half fibrous loam; the remainder may consist of peat, silver sand, and some drainage material, like finely broken potsherds or soft brick. It requires an intermediate temperature. In the rearrangement of Orchid genera by Bentham in the "Genera Plantarum," he has separated this species and *C. elegans* from *Cymbidium*. They now constitute a new genus—*Cyperorchis*.

**Plum Wyedale.**—I cannot quite agree with "W. G. C.'s" remarks with regard to Wyedale Plum (THE GARDEN, page 390). "W. G. C." thinks it is because of the small size of the fruit that it is not more largely grown. I think it is because it has not been advertised much. It is a grand late cooking Plum, but for dessert it might do to look at, and that is all. The Blue Imperatrice and Ickworth Imperatrice come in for dessert at the same season, for they will hang a long time. I have often gathered them in November. About twenty-six years ago the first Wyedale Plum tree was planted in the Bickley Garden, Kent, and a year or two after some heavily-laden branches of beautiful fruit were taken to one of the Crystal Palace shows, but it did not then, as now, gain notice. Quite likely this was the first time it was exhibited. At Farnborough, in Kent, it was grown, I should think, between thirty and forty years ago for supplying the London market, and twenty years ago it was plentiful in the Brighton market.—JAMES NEIGHBOUR, *Coppel Hall Gardens, Epping.*

**Snowdrops.**—The beautiful illustration of these lovely early spring flowers naturalised (p. 395) recalls to my mind many similar spots, notably at Linton Park, near Maidstone, where the Snowdrops had been left undisturbed for many years and had spread out into broad masses under the overhanging branches of lofty forest trees. The finest beds of them were under Lime trees. Then there were winding rows or edgings to woodland walks, and clumps and masses in all directions, for the bulbs flourished so well in the Kentish soil, that one had only to scatter the bulbs and cover them with soil and leave them alone, and a good bed was soon formed. But it

must not be supposed that they will luxuriate anywhere and everywhere in the same way, for since I have resided in Hampshire I have planted thousands of bulbs in the hope of getting them to increase, but they all die away after the second or third year. It seems as if they are not at home in such close proximity to the sea. In a nursery close to a town where every foot has to be cultivated there are none of the mossy banks and grassy glades that appear to be necessary for Snowdrops. Although I have seen nearly every kind of cultivated bulb grown and flowered to perfection in pots, flower beds, and borders, I have never yet seen Snowdrops looking really happy except when left alone, as shown in the illustration.—JAMES GROOM, Gosport.

**Anthericum lineare foliis variegatis.**—This was sent out about 1880 under the name of *Anthericum Makoyanum*. It has the habit of the type, but grows larger. The leaves are  $\frac{1}{2}$  inches broad, 15 inches long, with a beautiful, distinct, large, creamy white or yellow margin, giving the plant the aspect of a small *Pandanus Veitchi*, and a rich ornamental character. It produces a striking effect planted in the open ground as an edging around large beds in a half shaded position, or as a carpeting under trees or large tropical plants, such as *Wigandia*, *Caladium esculentum*, it is invaluable. If grown in pots or lifted from the open air in autumn and potted it will be found a capital plant for greenhouses, conservatories and drawing-rooms, and its fine variegated leaves will last all through the winter without any special care. It is very strange indeed that such a worthy plant is so seldom seen in gardens. It is easily cultivated and prefers a light porous soil, say leaf-mould, peat and sand in equal parts, plenty of moisture in summer and moderate waterings in winter. When the soil is too rich, the leaves are not so distinctly and brightly variegated. Plant out in May, take up and repot in September, and winter in a temperate house. It is easily propagated in spring by division of the numerous offsets, by the bulbils produced on the stems, sown as soon as ripe in pans and kept in a greenhouse, and by seeds, which are freely produced.—D. GUIHENEUF.

**Selenipedium Schlimi**—Amongst the Lady's Slippers of the New World (which, compared with those of the Old, are few in number) there is none more interesting to cultivators than this. It is the only one of the group whose flowers are not largely green in colour, in this instance being almost entirely white and pale rose. The flower is  $\frac{1}{2}$  inches or a little more across, the curious inflated lip having a very small opening. All the parts of the flower are covered with a soft pubescence. The leaves of this species are narrow, as a rule less than 1 foot long; as in all the *Selenipediums*, they have a long pointed apex. It has always had the reputation of being difficult to keep in health, but there is a plant now flowering in the collection at Kew which has been there for fourteen years. It is probable that plants of this species are often kept too hot; it appears to thrive better as an intermediate than as a stove plant. Another point in its cultivation is, that even more than other Lady's Slippers does it revel in abundant moisture. Although so frequently unsatisfactory in health itself, it has, by being fertilised with other species, produced a progeny which in robustness and vigour is certainly the equal of any other hybrid *Oreohids*. Of those raised from it, it is only necessary to mention *S. Sedeni*, the first of one of the most useful races of hybrid *Oreohids*. It has, however, been surpassed in beauty by others of closely allied, but later origin, most of which we owe to the skill of Mr. Seden.

**Trichosma suavis.**—Over all the broad surface of our Indian empire there is no area that, for its size, contains more to interest the naturalist than the comparatively small district known as Khasya. Among the many fine *Oreohids* which hail from there, there are many which no doubt surpass *Trichosma suavis* in showiness, but there is none more sweet and charming. It is an old

*Oreohid* in English collections, having been first imported fifty-five years ago, but at the present time it is far from common. It has thin, erect, tapering stems about 8 inches high, each of which carries a pair of oblong, bright green leaves. The flowers, which are usually at their best in November—and not in spring, as has so frequently been stated in books—are produced six or eight together in a raceme which springs from between the two leaves. The sepals and petals are creamy white, whilst the lip has its side lobes white, striped with a rich brownish red, and the central lobe yellow, with a crimson margin. Each flower is about  $1\frac{1}{2}$  inches in diameter, and has a delightfully sweet fragrance. This *Oreohid* has been placed under the genus *Calogyne*, to which it is undoubtedly closely allied, but it differs from that genus in its narrow, erect stems and Lily-of-the-Valley-like habit. As has already been intimated, it is not very much grown in England, but when it is, it is as often as not treated wrongly by giving too high a temperature. It is a cool intermediate plant, and will thrive at the warmer end of the *Odontoglossum* house. It should never be given greater heat than that of the *Cattleya* house, and this only when in active growth. It should be potted in peat and *Sphagnum* and kept moist at all times.

## PUBLIC GARDENS.

**Open spaces.**—The monthly meeting of the Metropolitan Public Gardens Association was held at 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding. It was agreed to offer to open some additional school playgrounds on Saturdays, to contribute towards the purchase of the Guy's Hospital disused burial-ground, S.E., and to undertake the laying-out of the ground, to improve and furnish seats for the enclosure round St. John's Church, Smith Square, S.W., to acquire a small burial-ground in Long Lane, S.E., to add to the adjoining one (now being laid out for public recreation), and to draw the attention of the London County Council to the vacant site in Compton Place, Hunter Street, W.C., with a view to its remaining unbuild on, in the midst of its crowded surroundings. It was announced that Lord Meath had opened to the public Bartholomew Square, E.C., on the 5th inst., which had been acquired by the St. Luke's Vestry through the instrumentality of the association, towards the laying out of which it had also contributed £182. Amongst many matters considered at the meeting were the proposed acquisition of the Copperas, Bromley, E., Brixton Oval, a large park at Muswell Hill, N., a site in Deptford, the churchyards of St. James's, Pentonville, and St. James's, Piccadilly, Falcon Court, S.E., and Ham Common, S.W.

**The weather in West Herts.**—On the 22nd the temperature in shade rose to 54°, but since then the weather has remained cold, and during the night preceding the 27th the exposed thermometer showed 9° of frost. The change is shown by the temperature of the ground, which five days ago at 1 foot deep was rather in excess of the average for the month, but is now about 3° colder than is seasonable. In the first half of the present month 3 inches of rain fell, but since then only about half an inch has fallen. A few flakes of snow, the first of the season, were noticed on the 23rd, but were almost immediately followed by sleet and rain. During the last three days the wind has come exclusively from some easterly point of the compass, while the air has been drier than of late both during the daytime and at night. The sun shone for only about two hours during the week, and on four days no sunshine at all was recorded.—E. M., *Berkhamsted*.

**Treatment of lawns.**—Mr. F. W. Burbidge in his welcome article on this subject writes, when referring to "a home made mixture," to

apply same "at the rate of 10 or 12 tons to an acre." This means something like 6 lbs. of a not very handsome carpet per square yard. On the other hand, he gives a mixture weighing 10 ewt. only, which is stated to be sufficient for 5 acres of lawn. Now to treat 5 acres of lawn with the home-made stimulant it would take 60 tons of stuff, which has to be collected, turned over, dried, screened, and spread. All this preparation, with wages at 3s. a day, would cost, I should think, infinitely more under any circumstances than the recipe containing a proportion of chemicals. I have a weed here which they call heal all, or "ecl all," which is eating up my lawns, and for which I can find no remedy. It lies so close that the machine does not touch it. It roots at every joint and bears a small purple, cone-shaped flower, like a Clover. The knives of the machine cut off the pods, throw the seed forward, and the machine roller carefully rolls them in. A new lawn I sowed most carefully a few years ago is now disfigured with islands of it. Would nitrate of soda put on in winter destroy it?—J. W. S.

**Presentation to Mr. Davidson.**—We regret to learn that owing to ill-health Mr. Davidson is about to resign his charge of the seed department of Messrs. Veitch's nursery at Chelsea, after thirty years' service. A pleasing feature of his retirement is the presentation to him by his fellow workers of a handsome timepiece and candle sticks with an illuminated address, as a token of the esteem in which he is held by those who have so long worked with him.

**Swainsonia Veitchi (?)**—In reply to our correspondent, Mr. Fulford (page 300, October 19), we have ascertained that the *Swainsonia* noted as above is not known to the firm whose name it bears. It is assumed that the name is a local one. Without specimens of this and *S. galegæfolia* alba for comparison we cannot say whether they are identical, but we surmise as much. *S. galegæfolia* is a very variable species, and possibly there may be two distinct white forms.

**Synonymous Grapes.**—What is the difference between the Muscat of Alexandria, the Bowood Muscat and the Tynninghame Muscat?—L. M.

\* \* \* Mr. Barron, in his "Vines and Vine Culture," classes these as synonymous.—Ed.

**Names of plants.**—*J. Bennett*.—Your *Cypripediums* are correctly named; in no case is the appellation *superbum* warranted.—*C. B.*—Your *Euchaisites*, from the appearance of the roots, have evidently become water-logged. We hope to refer to the subject in a coming issue.—*A. Peake*.—We cannot undertake to name florists' flowers.—*Evelyn*.—The Spindle Tree (*Euonymus europæus*).—*A Reader*.—1, *Ixora javanica*; 2, 1. *Fraseri*.—*A. Ducre*.—*Vaccinium pennsylvanicum*.

**Names of fruit.**—*C. C.*—1, Worcester Pearmain; 2, Small's Admirable; 3, Betty Geeson; 4, Emperor Alexander; 5, Lord Suffield; 6, Alfriston; 7, not recognised; 8, Beurré Capiaumont; 9, Thompson's; 10, Doyenné du Comice; 11, Easter Beurré; 12, Glou Moreceau.—*T. Lester*.—1, Doyenné Boussoch; 2, Glou Moreceau; 3, Chaumontel; 4, Glou Moreceau.—*J. A. R. Greaves*.—1 and 2, Beurré Hardy; 3, Swan's Egg; 4, not recognised.—*A. G. J.*—1, Apple King of the Pippins; 2, Yorkshire Greening; 3, Beauty of Kent; 4, Pear Beurré Diel; 5, Haeon's Incomparable.—*W. Sangwin*.—Searlet Noupareil is Crimson Queening; Duke of Cornwall not recognised; Court Pendu Plat is probably Rymer; the other sorts you send are true to name.—*W. R. L.*—1, Catillac; 2, Vicar of Winkfield; 3, Norfolk Beaufin; 4, White Calville; 5, long fruit Marie Louise; 6, russet fruit Beurré Hardy.—*W. Newton*.—Pear Urbaniste.—*W. West*.—1, Emperor Alexander; 2, Beauty of Kent; 3, Bedfordshire Foundling.—*W. J. G.*—1, Louise Bonne of Jersey; 2, Knight's Monarch; 3, Beurré Hardy; 4, Catillac; 5, Verulam; 6, not recognised; 7, Urbaniste; 8, Baronne de Mello; 9, Old Colmar; 10, Easter Beurré; 11, Beurré Capiaumont; 12, Beurré Diel; 13, not recognised; 14, Marie Louise; 15, Beurré Bosc; 16, not recognised; 18, Aston Town; 19, insufficient specimen.

No. 1255. SATURDAY, December 7, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHARD AND FRUIT GARDEN.

### STEWING PEARS.

VALUABLE information has been given in the pages of THE GARDEN for years past on the merits or otherwise of our different Pears, especially dessert varieties, but I feel there still remains a deal to be said in advocating the merits and general usefulness of the stewing varieties. To recommend the planting of a few of these in small gardens may appear at first doubtful advice, but I think it can easily be shown that in such a case they may prove equally as valuable, and certainly more serviceable than some of the best dessert varieties. With the latter, where only a limited number of trees can be grown, a succession of ripe fruit can only be had over a very brief period, and in such cases it is seldom that a proper fruit room is available where late varieties can be properly stored and ripened, with the result that when fruit is most acceptable, the small grower has to buy or go without. Again, dessert varieties, unless well cultivated and close attention given afterwards to gathering and storing the fruit, may prove most disappointing as regards flavour, and a Pear, like any other fruit, cannot, or should not, be appreciated for size and appearance alone. Now I maintain there are several advantages in the stewing Pears over dessert varieties, especially in small collections, which I will endeavour to point out. In the first place they are naturally hardier in constitution, and seldom fail to produce good crops when proper attention is afforded. From the same tree a succession of fruit may be had during the whole winter months, and when these are properly cooked and served they not only surpass inferior and badly ripened dessert varieties, but, what is more, invalids are allowed to partake of them freely when probably all other fruit in a raw state is denied. This alone I consider is enough to recommend the more general cultivation of stewing Pears. Another advantage is the fact that no proper fruit room is required in which to store the Pears, as they keep perfectly in boxes or hampers so long as they are cool and dry.

I have been led to make the remarks on this valuable fruit after seeing a number of collections of Pears at our autumn shows, where stewing varieties fail to meet with the appreciation which I consider their general usefulness merits. Only recently a case in point came under my notice where a good collection of eight dishes was passed over because it contained one of a stewing variety. In this instance it was certainly out of place, as the schedule stipulated they should be dessert varieties, but even had this been allowed and the collection awarded first prize, many, I fear, would have condemned the judgment and looked upon this as a coarse dish, while had it happened to have been a dish of Pitmaston, it would have been passed over without comment, even had the latter been approaching a state of rotteness. I would strongly recommend framers of schedules to allow a dish or two of stewing Pears in the collections, or offer separate prizes, say for the heaviest dish of these, which I think would

greatly assist in bringing them more under public notice, and also increase their cultivation.

R. PARKER.

*Goodwood.*

**Best flavoured Pears.**—In the notes by Mr. Burrell (page 379) the following sentences occur: "Our two best Pears have again been Doyenné du Comice and Beurré Superfin. Possibly the next best, from a flavour point of view, are Marie Louise, Thompson's, and Winter Nelis." Now no grower of experience will question the substantial merits of the two first-named Pears. But whether of the five they should lead for flavour admits of wide differences of opinion. Were I to put Winter Nelis at the head of the best for flavour there would probably be hosts of dissentients. Possibly the larger number of growers would elect Marie Louise as leading for flavour. But my chief objection is to Thompson's being bracketed as equal in flavour with Marie Louise or Winter Nelis. I have tasted Thompson's of good quality, and doubtless it is well grown and finished at Claremont, but I have never yet met with it as in the running for flavour with the other four named. Mr. Burrell's four are all good. It is a mere difference as to which should claim pre-eminence in flavour. I also think it a mistake to include Thompson's among the five best for flavour.—D. T. F.

**A new Red Quarrenden.**—The very richly coloured and beautiful Apple to which an award of merit was given at the Drill Hall on the 26th ult. under the name of Stubbs' Seedling should take a high place in time in market lists. Naturally it is assumed that all which is said as to its excellent cropping qualities is true. The fruits are exact reproductions of the Devonshire Quarrenden in its best, cleanest, and richest coloured form, but whilst the flesh is soft, sweet, and exceedingly pleasant eating, it is quite white, whilst in the true Quarrenden colour is often strongly diffused through the flesh. If any appellation could fitly describe this new Apple it would probably be Winter Quarrenden, only it is not well to have in fruits names that may lead to confusion. For so highly coloured a fruit, this Apple seems to be unusually late.—A. D.

**Colour in Blenheim Orange Apple.**—Although it is now some twelve years since I came here, I have never seen what might be called a well-coloured specimen of the Blenheim Orange Apple that had been grown in the midlands. The fruit of it in this district, even on healthy trees, is decidedly smaller than the type and comparatively green in colour, nor does it improve much in this respect after being kept. Other Apples, such as Mère de Ménage, Cox's Pomona, King of the Pippins, and even King of Tompkins County carry a good colour, but Blenheim refuses to do so even on an espalier. The quality also is inferior to that of fruit grown in the south. I have seen Blenheim almost crimson gathered from trees in Essex, Kent, and Buckinghamshire.—J. C. Newark.

**Pruning illustrated.**—In the excellent article (p. 380) by Mr. Fenwick there is a good suggestion. It has often occurred to me that one practical demonstration is worth a dozen dry lectures, and if articles on pruning were illustrated showing the difference between trees that had been well cared for and others that had been allowed to grow wild or had been backed about in that barbarous manner some people call "pruning," readers would then be able to judge for themselves which was the right mode of treatment. There are quite as many trees spoiled by a too free use of the pruning knife as there are by it not being used at all.—H. C. P.

**Pear President d'Osmonville.**—This appears to be but little known, yet in its season (November) there is no Pear to surpass it in flavour. To place it equal with Josephine de Malines is to put it very high in the list of first-class flavoured Pears. It deserves that position, as the flavour is not only rich and juicy, but the

flesh very fine in the grain. In that respect it is the counterpart of the variety just named. The tree makes a handsome close pyramid and on the Quince stock grows freely. The only fault I have to find with it is that it does not fruit freely in a young state, but trees seven and eight years old bear regularly. If I had a wall 10 feet to 14 feet high to furnish, I should plant this variety in preference to Beurré Diel or any other sort that ripens at the same time. President d'Osmonville is just the sort to plant in a strong heavy soil where it can have a wall with an east or west aspect.—J. C. CLARKE.

### EFFECT OF SHADE.

NOR till a comparatively recent date did I fully realise the great difference discernible in the growth of plants, Vines and trees that derive the full benefit of all the light and sunshine going as compared with those not so greatly favoured. The effect of sunshine, more especially on young growing plants, is most marked, and although a believer in temporary shade for certain kinds under glass, I am yet more chary of shading than heretofore. Private gardeners of an observant disposition may have fair opportunities for improving their mind and seeing and noting much that the superficial observer fails to detect, but place the same men in the class of houses erected by market growers and they will then soon discover that there is still much for them to learn. As a rule, very much more sunshine and light reach the contents of market growers' houses than is the case with the majority of old-fashioned glazed structures in private gardens. This alone would partially account for the heavier crops on the Vines and fruit trees, and the dwarfier, more free-flowering plants in the former, and it is no discredit, therefore, to the latter if they are beaten in some instances by market gardeners. When from any cause very little sunshine reaches plants their progress is slow and otherwise unsatisfactory. I will take Tomatoes as an instance. If these are planted in rows across a large span-roofed house, with high brick walls and no side lights, all on the shady side, or say that are shaded by the walls for several hours in the morning, they will grow very slowly and feebly indeed. So marked is this slow progress, that I seriously question whether it is not false economy dispensing with side lights in the first instance. Not only does the sunshine where it strikes during the greater part of the day hasten the growth of the plants, but it also solidifies their stems, rendering them more disease-resisting than is the case with those partially shaded. Unduly crowding the plants may not affect them greatly at the outset, but directly they reach a height of 3 feet or so they begin to shade and weaken each other, severe defoliation being but a poor way out of the difficulty. For the future our rows will be not less than 3 feet apart and another foot will be allowed in some positions. The hottest sunshine does not injure Tomato foliage in the least, but I am under the impression a little light shading might save many fruits from being scalded—the fate of tons of Tomatoes last summer. Nor will the fruit set during the dull months of November and December, and those who would have good ripe Tomatoes during January and February must have them set on the plants before November—that is to say, before sunshine is a very scarce commodity.

The effect of shade on young Grape Vines is even more marked. Last season a considerable number of newly-struck Vines was planted down each side of a large span-roofed house partly with a view to save the trouble of keeping them in pots and partly with the idea that they would

become well rooted and grow away all the more strongly next season. That the canes of these same young Vines might have been grown to a great length this year I know, but not if they have to contend with Tomatoes for both light and moisture. The latter were of the greater importance, and conditions favourable to the production of heavy crops were, therefore, maintained. My point is this: Wherever the Tomatoes shaded the Vines, and they were very close up to them, the Vines made scarcely any progress, but in all instances where a fair amount of sunshine reached them respectable canes have formed. When, then, private gardeners plant Vines against side walls and occasionally almost underneath a latticed staging, they need not be surprised if the progress they make is unsatisfactory. Even if the start is made with strong, well-ripened canes it would yet be better to assign these a lighter position, as it is very certain they would make better progress and form more serviceable stems if lateral growths could form on them every year. For many years past I have contended against the practice of planting Vines in a narrow space between hot-water pipes and front walls, believing that it would be far better to give them lighter positions, also well away from the pernicious effects of over-heated pipes. Grape Vines will really fruit all over the border of a house, always provided they do not unduly shade each other from the ground upwards, and so they will against back walls if only a fair amount of sunshine reaches them. It is not the Vines that form, or are allowed to form, the most lateral or running growth that are making the most satisfactory progress, but rather those grown in the full sunshine and furnished with a moderate quantity of primary leaves only. On examining a number of young Gros Colman Vines that have not been allowed to form any superfluous growth or other than the leaf or two left on the lateral growth of the canes, I was delighted to find how strongly they are rooted, the surface soil being crowded with root fibres. The border as well as the Vines got the benefit of a large amount of sunshine, and they in addition had water as often as Tomatoes near at hand got it.

Peach and Nectarine trees, again, make extraordinary progress in market growers' houses. They may branch and branch again, and yet if thinned out properly there will be little likelihood of the wood failing to ripen properly and flowering freely. It is possible to plant maidens in the spring of one year and fruit them the following year. A tree of Sea Eagle that I had planted in March, 1894, matured two dozen fine fruits this summer, and several other trees gave comparatively heavy crops, yet they look none the worse for it, and pruning them is quite a pleasure. By far the best results were obtained from trees planted on the east side of a span-roofed house, these getting much more sunshine than those on the west side. The latter have attained to the greatest size, some of the maidens planted during the month named covering a roof area 12 feet by 7 feet, but the wood is not so well matured nor the flower-buds so plentiful and plump as they are on the more favoured trees. All the credit, however, must not be given to the sunshine, but where the rafters on a roof are heavy and thick, and other obstacles are offered to the free ingress of sunshine, it is not to be expected that serviceable trees can be formed so quickly.

When Vines, trees, or plants are grown in the roomy and very light structures mostly favoured by market growers, and now largely superseding the older and more expensive styles in private gardens, they will stand far more

glaring sunshine without burning, or even suffering from attacks of red spider, than is the case with the more flimsy-leaved occupants of houses not so lightly constructed. Take Cucumbers, for instance. It is really surprising how much sunshine the leaves will stand without burning if only they have been well hardened previously. Not but that temporary shade is beneficial at times, especially if there is any likelihood of a failure to keep up plenty of moisture in the atmosphere. We are in the habit of associating red spider with Peach trees and Vines when these are not freely syringed during the greater part of the growing season, but my Vine leaves have kept perfectly free of them, and only those Peach trees in a very hot and none too well ventilated corner were infested with spider, yet neither the Vines nor the Peach trees were once syringed all the season. Tomatoes had to be studied, and I prefer to keep these in a dry atmosphere. But if I did not syringe or supply moisture overhead, I did not forget that there was all the greater need to supply abundance of water to the roots. According to my experience, trees, Vines, and plants want, and must have, in fact, twice as much water and liquid food as is required by the same class of trees, Vines, and plants growing in more shady quarters. Being grown in the constantly stirring atmosphere of long ranges of glass and in the full sunshine, the leaves are of the greatest substance, resisting excessively hot sunshine as well as insect attacks far better than those not so exposed, and which also are frequently syringed and kept in a somewhat stagnant atmosphere.

W. IGGULDEN.

#### THE KEEPING PROPERTIES OF APPLES.

COMPLAINTS are rife as to the early decay of Apples this year, and I have noticed similar complaints in former seasons of plenty when the summers have been abnormally hot and dry. This is owing in part no doubt to the planting of too many early varieties, which makes it difficult to get rid of the fruit in its proper season when the crop is great. There is, however, a reason for fruit decaying quickly after such summers, especially where it is allowed to hang as late as possible on the trees, and that is ripening too early. My experience is that when wanted for long keeping and for flavour, most Apples should be gathered before they become so forward as to part very easily from the trees. I hold that there should be no further delay about gathering the crop when the fruits will part from the wood at the proper place, and that any delay after this tends to spoil their quality and keeping properties. To give a case or two bearing on the matter, I may say that the most highly-coloured and biggest Ribstons that have not been already used and which were almost dead ripe when gathered have become mealy and flavourless, while those fruits which showed less of the red and yellow when gathered are now first rate in flavour and texture, will never become mealy, and will keep for an indefinite period. Fruits of Manks Codlin which were gathered quite early are very firm, of good colour, and there has been no decay amongst them, but had they been left on the trees until they parted freely, I should now have had none left. As it is, however, there will be plenty of this excellent cooking Apple to carry me through November, a late date for Manks Codlin. Of course, we must not err on the other side and gather too soon, or the fruit will shrivel and be flavourless, but there certainly is a golden mean that watchful experience only will teach, and that must be learned by those who would extend the season of the best varieties of Apples.

In his notes on the Crystal Palace fruit show, "A. D." (p. 332) suggests special classes for late varieties as worthy of consideration by the officials of the R.H.S., and with this I cordially

agree. I should like, however, to see late varieties exhibited at a show held in December, January or February, and do not think it is too much to hope that such a show should be initiated, for it would do much good in encouraging the planting and proper storage of late Apples. Summer shows rather encourage the growth of early varieties to the exclusion of those which are more valuable. At a winter show we should probably see but few overgrown samples or any grown under glass, but what was lost in display would be more than gained in utility. Apples are more needed in winter than at any other season, and it is just as necessary to learn how to gather and store the fruit as it is to learn how it should be grown.

J. C. TALLACK.

**Apple Fearn's Pippin.**—This variety is worth growing on account of its free-bearing qualities. With me when the tree has attained a little age it never fails to crop. At one time before the introduction of larger and more showy kinds, Fearn's Pippin was one of the best market varieties. I do not advise its culture for sale, but as a reliable cropper in private gardens of limited extent it is valuable.—S. H. B.

**Apple Ashmead's Kernel.**—This Apple is worthy of a leading position among good dessert varieties. We have none too many really good late dessert Apples, but this is one of the very best, keeping good well into the spring, at that late period being sweet, firm, and of first-rate quality. The fruits, under medium size, are round, of a light russet colour. If not gathered too soon and stored in a cool place this Apple will keep until May. When I lived in Gloucestershire this was much grown and one of the most liked dessert Apples; in fact, it was always relied upon as the latest dessert variety. It fruited grandly as a standard on the Crab, but the fruits were small. I have it as a bush on the Paradise and it bears well, but the fruit does not keep quite so long. The tree does not like severe pruning. It makes a nice pyramid, and is well worth adding to collections of fruit trees where quality is desired. It forms a good succession to Cox's Orange Pippin.—G. WYTHES.

**Apple Jefferson.**—At several prominent fruit exhibitions this Apple has been staged in excellent form, its beautiful shape and handsome colour being very striking. I believe the variety is of American origin, and this season appears to have suited it, as I have never seen it so well developed. Some growers speak enthusiastically of its strong and prolific habit and delicious flavour. In my opinion Jefferson has always a peculiar musty flavour that I dislike. I have tasted many fruits of the variety that have been sent me to name, and also at several fruit shows, and this musty taste was present in all. We have many better varieties equally as handsome, prolific, and as well or better flavoured in use at the same time (September and October), and there is no necessity for planters to purchase any variety of doubtful character. What all planters should aim at is a choice selected list of comparatively few sorts.—W. R. H.

**Quince.**—It is doubtful if better or more general crops of this fruit were ever produced than has been the case this year. Many trees that have seldom produced a fruit were this autumn loaded with beautiful golden fruit of large size. The finest dish I ever saw was staged at Gloucester fruit show on November 11 by Wm. Sowray, Highnam Court Gardens, near Gloucester. I believe each fruit would scale 1 lb. or upwards, the variety being the Pear-shaped, which is the best to plant for home use or market. There are five or six other varieties; amongst these may be mentioned the Apple-shaped and Meech's Prolific as following the first named. All the varieties succeed well in a damp situation, but, provided the soil is rich and deep, good crops may be expected in those seasons favourable for the trees cropping. Like all other fruit-bearing trees, good culture tells with Quince. Many failures may be attributed to neglect, such as permitting

the head of the tree to become a tangled mass of growth or starving at the roots. On several occasions I have seen formerly barren trees brought into a fruitful state by a gradual thinning out of the tops and the encouragement of fresh, sturdy, clean shoots that have been left their full length at pruning time. In many gardens the Quinces are simply stuck in in some out-of-the-way spot and are never touched with the knife or given any manure from one year's end to another, for being out of sight or away from the usual routine of work they are forgotten in the press of other work. If annually manured and treated as other choice fruit trees, the results will be of a profitable nature. Sewage and liquid manure are of immense service during the summer months to trees bearing a full crop, the fruit acquiring a colour and clearness in the skin not seen in the produce of those trees that are ill-fed.—W. R. H.

**Apple Duke of Devonshire.**—This excellent dessert Apple is much more appreciated in the north than in the south and west. As a proof of this, it will be found on examination of the schedules that prizes are always given at the Edinburgh September shows for this variety. Many gardeners in Scotland speak in the highest terms of its productiveness and good quality in that portion of the kingdom. It is worth planting much more frequently in England than has been the case, as it is one of the most valuable Apples we have for private use. As stated, the quality is good and the fruit of a suitable dessert size, keeping well till the end of May. The tree is a strong, vigorous grower, hardy, and does well in all forms of growth. No Apple that I know will keep sound for such a long period after being blown down by gales from tall trees. I have had fruit thus fallen from standards five months afterwards that did not exhibit any signs of decay.—W. G. C.

#### NOTES ON PLUMS.

IN the returns published from growers of these fruits over a wide area how great is the unanimity shown in relation to the fruits' value in various ways. We may well regard the position of the Plum, both as a garden and market fruit, as indelibly established. That in the north there are districts in which the Plum does not thrive outdoors is very probable, and no one would advise culture under such conditions. Happily, however, Plums thrive well nearly all over the kingdom. Still further, although growers express their opinions largely in favour of a deep, retentive, loamy soil, yet the Plum seems to do well almost everywhere, thus showing how very accommodating it is. Most certainly where lime is naturally furnished or is artificially supplied Plums seem to be most at home. Not in all cases, however, is it found advisable to grow the best flavoured varieties in the open ground. Some situations being naturally warm and sheltered enable the best of varieties to do well as bush trees, but generally these are better on walls, where, too, they can be all the more easily protected from birds and wasps. Walls, too, furnish such varying conditions of aspect, that it is easy to have a greater succession than would be possible on open grown trees. When we start with Rivers' Favourite, the earliest of all the best-flavoured section, in July, and continue with other varieties down to November with Coe's Golden Drop and Purple Gage from a north wall, certainly the Plum then becomes a high class and reliable dessert fruit. Of course, the late varieties named will not hang on the trees so long as November, but they will keep well in a cool store for a month at least, and thus they may be had, if a little shrivelled, at least very delicious, till so late a period. To find a choice selection of highly-flavoured Plums for wall culture, it is but needful to turn to the reports recently published and note varieties often mentioned. There seems to be, in fact, no difficulty in selecting twelve varieties all of which give good flavour, especially for dessert, many of them also varying in colour

and form. That is enough to satisfy all reasonable requirements. As to cooking Plums, most of these may be grown very well indeed in the open, and it seems a pity that walls should be devoted to the growth of Victoria, Pond's, Magnum Bonum, &c. A select list of half a dozen of the very best for average culture, reservation being made of others that may seem best for certain districts, would comprise Rivers' Early Prolific, Czar, Victoria, Pond's Seedling, March and Archduke. Probably Victoria would never be left out of any selection, yet there remain Orleans, Gisborne's, Pershore, Diamond, Sultan, Mitchellson's, Belle de Septembre and others to furnish other selections, or extend the original one to a dozen varieties. The Plum under all ordinary conditions does well as a standard, because the roots are less gross than are those of standard Apple or Pear trees, and the growth is rarely so robust when grown as bush or pyramid trees. Much pruning and pinching are needful, and sometimes root-pruning is requisite to correct a tendency to produce excess of wood. On walls, however, there is no great cause for complaint as to undue luxuriance unless there be excess in manuring, which is always bad practice. Stone fruits need a good supply of phosphates to assist in forming stones, and possibly constituents of this description may materially help to create high flavour.—A. D.

— Although many, perhaps the majority of gardeners may have not much to do with Plums as orchard trees, at any rate on a large scale, one and all have doubtless realised the value of this fruit both from a dessert and cooking standpoint, and the special notes that have lately appeared will be of great interest. The value of the Plum in private gardens has been considerably enhanced of late, from the fact that with the introduction of new varieties, a little care in planting can so prolong the season as to secure fruit for both purposes above named at least three months out of the twelve. Having had the planting of a Plum wall some 150 yards long by 12 feet high, and the opportunity of watching the development of the trees to the complete furnishing of the wall, I have been much interested in noting the habit of different varieties and the treatment essential to the early production of a good annual supply of fruit. There is a very great difference in the style of growth, some sorts making a lot of wood, necessitating root-pruning at an early stage, others hardly any annual growth, but bristling with fruit buds right away from the first year of planting. The range of dessert varieties extends from Early Favourite to Coe's Golden Drop and Ickworth Impératrice, and includes besides these the old Green, Oullin's Golden, and Transparent Gages, Jefferson, Kirke's and Denniston's Superb, and the cooking sorts from Early Prolific to Coe's Late Red, including Czar, Victoria, Diamond, Pond's Seedling, and Imperial de Milan, in the order of their ripening. A great many varieties of cooking Plums are hardly advisable. What one wants are successional first-rate croppers of good average size. Of the cropping qualities of the sixteen varieties above enumerated, now that they are well established on the wall, I can write in the highest terms. A failure is only brought about by an exceptionally cold spring and the destruction of the bloom by frost. The blossom of the Plum, it may be noted, is somewhat sensitive, especially if a frosty night follows a damp day, owing to the fact that many of the flowers on spurs face the weather, and consequently retain the moisture in the cup. When this is the case a slight frost is enough to destroy the greater part of the bloom. A double thickness of half-inch mesh fish netting, failing a supply of tiffany, will be found a good spring protection. Denniston's and Pond's Seedling are the least productive of the varieties grown and want root-pruning every third year, whilst, on the other hand, Early Prolific and Early Favourite, Transparent Gage, and Coe's Late Red are all fruit buds, and want feeding to encourage the growth of wood. I planted in addition Washington and Reine Claude de Bayay, but have been

obliged to discard them; the one is very shy and the other makes a lot of big sappy wood that is not amenable to root-pruning. If the big roots are cut back the shoots canker badly and die back. The three chief enemies of the Plum are bullfinches, the grey aphid and wasps. Where the first-named are locally troublesome it is useless attempting Plum culture in the open except on a large scale; a few bushes and standards stand but a poor chance against them. Wall trees can be netted, keeping the netting clear of the trees by the aid of a few forked sticks, this being the most effectual means of warding off the attack. The grey aphid is occasionally very troublesome, necessitating frequent syringing to keep the foliage clean. I have found quassia chips at once the most effectual and the safest remedy. For wasps the best plan is an early hunting for, and the prompt destruction of, nests. Traps in the way of bottles are of little use, the insects preferring ripe Plums to the counter attractions of sugared beer. Late Plums have to be netted against blackbirds, or these birds will carry them off wholesale when they have finished up the smaller fruits. On our light, dry soil I find a good surface-mulching absolutely essential in seasons like those of 1893 and 1895; a compost of three parts heavy manure and one of road sidings is used, and is placed rather more than a yard all round the trees, taking the stem as a centre. Thinning is also an essential feature towards the production of good fruit, especially with the heaviest croppers.—E. BURRELL, *Claremont*.

— Although all Plums—as standards, pyramids and bushes, as well as on walls—do remarkably well on our light, brashy soil, with seldom a light crop, and are far better than Cherries and Pears, and even Apples, still I consider extension of orchard planting is not advisable in this district unless there was a prospect of a fresh market, for I have an idea (although practically I know nothing of marketing the crop) that the present supply is fairly adequate for the local demand, excepting for choice dessert kinds; but as these would necessitate special treatment and in some cases wall culture, orchard planting is not applicable to them. Very much, however, might be done by replacing inferior sorts (of which far too many are still grown in this neighbourhood with better varieties, a course I would recommend in preference to adding a large acreage of Plum orchards. Where all kinds are a rly satisfactory it is needless to particularise varieties, but I may mention the Czar, Denbigh, Victoria and an early round black Plum carrying a heavy bloom, much smaller than any of the above-mentioned, but a grand Plum nevertheless (the name of which I do not know) as being—taking one year with another—as productive and useful as most. Of Damsons, the Shropshire and Prune are always satisfactory; the best flavoured are found amongst the Gages (the old one the sweetest), Kirke's, &c., to most of which a wall is allotted. Coe's Golden Drop might safely be included, but here during the last seventeen years it has not had a chance to hang sufficiently late to finish properly, owing to damp and wasps.—J. ROBERTS, *Tany butch*.

#### FRUIT TREES ON WALLS.

THE leaves have now fallen from most trees, therefore pruning and nailing may be proceeded with whenever the weather is mild. It is a great mistake to put men to such work when their fingers are so benumbed with the cold as to scarcely be able to hold the nails, for they cannot do the work satisfactorily, and much time is accordingly wasted. In order that the work may be completed before the sap rises, a good portion ought to be done before the turn of the year. There are many advantages gained by so doing. For example, take a north wall which is often covered with Morello Cherries. These take up much time in nailing, and should therefore be the first to receive attention. With me it is the rule to take a portion of the trees down each season, and to so regulate the shoots as to allow ample

space between them, and where there is a number of trees this takes up much time. If the work is commenced as soon as the leaves have fallen, and proceeded with whenever the weather will permit, it may be finished before severe frosts set in, thus enabling the borders to be manured and dug ready for planting. Early crops are usually grown on south borders, and as the walls facing this aspect are often covered with Apricots, Cherries, and Peaches, such trees are generally left till the severity of the winter has passed, by which time the borders are often planted. A couple of boards should then be used to stand upon in all cases, whether the ground is planted or not. It is the practice in some places to fasten the stout branches of trees to the walls with leather shreds; this is not the neatest form of securing them, neither is it the best, as they harbour insect pests. Tanned twine or yellow willow ties look much better and are equally as strong. Nothing adds so much to the appearance of a well-kept kitchen garden as neatly trained and well-kept fruit trees on the walls. I know from experience that it is no easy task to keep them in order at all times, especially where the staff is limited and much extra work has to receive attention just at the time the trees need it, but whatever is worth doing at all is worth doing well; therefore in large establishments a couple of hands ought to be spared to look after the walls if possible, and the trees will well repay for this extra labour bestowed on them.

It may seem an easy task to prune, but how many of us thoroughly understand the nature of the work, and unless a perfect knowledge be had, often more harm than good is done by the use of the pruning knife. It is useless to remove a shoot from the tree simply because one does not like to see it there. Some other object ought to be in view, namely, the production of fruit or inducing other growths to push where they are required. Many trees are ruined by a too free use of the pruning knife, the only result being a thicket of stout, ill-ripened wood the following season. What is wanted in all fruit trees is well-ripened wood studded with fruit buds. If we take note of the old orchard trees, we there find that Nature herself does the pruning, for it is seldom that any rank, ill-ripened growths present themselves, and if by chance a strong one does appear, if left alone we usually find that in a couple of years it is well covered with flowers. It should therefore be the aim of the gardener to assist Nature by so regulating the growth of his trees, that instead of being barren thickets they are fruitful branches. Nailing, too, is one of those operations that seems simple to look at, yet difficult to do properly, and one that requires a great deal of pains and attention before a person becomes proficient in the work. The operator should not only be able to drive in a nail without breaking it off, but should see at a glance the exact spot where a shred would be of the greatest service. He should also have an idea how long a shred ought to be in order that the shoot thus fastened may have room to expand. It often happens that the beginner puts the nail on the wrong side of the shoot, for, instead of looking which way the shoot is inclined to grow, he drives in, may be, the first nail, and when brought into position by the second shred the other nail is found to be pressing against the wood, and if allowed to remain so, usually brings on gumming or canker, often resulting in the death of the branch, thus disfiguring the shape of the tree. I have often seen it remarked that gardeners ought to be specialists. It is doubtful, however, whether such would remain long at the head where all kinds of produce are required. A good gardener should be proficient in every branch, otherwise he will not be able to dictate to those under him, and should anything go wrong he will not be able to explain the reason. It is no easy task to take down a Morello Cherry or Peach tree and put it back again so that every shoot may have ample space. To commence, the leading branches should be put in their places, and each lot of wood should be so laid in as in no way to appear as

though the branches would cross each other in a year or so; at the same time sufficient space must be reserved for laying in the young wood during the summer. H. C. P.

#### BLACK FLY ON PEACH TREES.

Would someone tell me how to rid an early Peach house of black fly? The trees are started early in February.—SUBSCRIBER.

\* \* Black fly on Peach and Nectarine trees is a great scourge and not easy of eradication. Where it was troublesome this year it will, unless somewhat drastic preventive measure are taken, be equally as numerous, perhaps more so, next season. Sometimes what are known as viviparous females survive through the winter, and, in any case, eggs are plentiful enough in a variety of positions on and off the trees at the present time, and only require the genial warmth of spring or a forcing house to hatch out perfect insects. After trying a variety of remedies, including hand-dressing of every portion of the trees with insecticides and a general cleansing of the house with only partial success in each case, I tried the effects of a petroleum dressing, with the result that black fly was no longer a bugbear. I should advise "Subscriber" to first give the woodwork and glass a thorough cleaning, also dressing the walls with hot lime-water made sufficiently thin to admit of its being well worked into all the crevices. This being done and the trees duly pruned, the next proceeding should be to clear out all rubbish and also remove the surface soil of inside border, many insects and eggs probably going with this. The trees ought then to be syringed with the petroleum mixture in preference to any more cumbersome method of dressing the trees. Use the water heated to 120°, and in each 3 gallons of this dissolve a lump of soft soap about the size of a moderately large hen's egg, prior to adding 6 ounces (to be measured with an ordinary 6 ounce or 8-ounce medicine bottle) of petroleum or paraffin, as generally, but erroneously termed. Apply while the water is hot, or otherwise it will not be nearly so effective, and keep the petroleum forcibly mixed and from floating on the surface either by returning every second syringe-ful into the receptacle or else by keeping two syringes going, one drenching every part of the trees and the other returning into the can. The petroleum mixture should be used very freely, as it is cheap enough, while if it does run down into the soil it is more likely to do good than harm. If a few eggs or insects escape and duly show on the trees, they must be met with a dose of tobacco powder, or otherwise they will soon be as numerous and injurious as ever. The petroleum mixture is also the best remedy that can be tried for brown scale, another very troublesome pest and only too common on Peach trees. If one application does not thoroughly cleanse a tree of this, give another, and if done before the buds are bursting, no harm whatever will accrue to the latter. The old surface soil of border containing the roots of trees that have been stunted in growth, owing largely to insect pests, should be replaced by a rich top-dressing.—W. I.

**Apples in Scotland.**—Many Apples are found in northern parts of Scotland bearing capably most seasons, while the same varieties may be seen poor in the southern parts of the country. But there are some varieties which are found to do well in nearly every district, notably Lord Grosvenor (some reference has been made to this most useful variety lately), which becomes a favourite wherever it is known. I planted a few young trees of it some years ago. They began to yield the year after they were planted, and never fail to bear each season heavy crops of large fruit. They are not of fine form, but that is of little consequence. Another Apple, always handsome, is Golden Spire, which is a free cropper in an untoward position, such as Grosvenor is in, and on cold and damp soil. These along with Seaton House, the freest bearer I know and valuable for cooking, give supplies of

fruit from September till April. Then Northern Greening and Yorkshire Greening finish the Apple season. Sandringham has fruited freely for two seasons past. The fruit is very handsome, large, and keeps late.—M. TEMPLE, *Carron, N.B.*

**Apple Warner's King.**—I am of the same opinion as Mr. Burrell (*THE GARDEN*, page 379) in regard to Warner's King Apple. For several years I grew it at Bickley, but often it would not keep longer than the middle of October. If by chance I could keep enough for a dish for exhibition during the first week in November, some of them have gone bad by the time a two days' show was over. This is too often the case with many of the big spongy Apples seen at our big autumn shows. No one would hesitate giving Yorkshire Greening the preference over Warner's King, but even Yorkshire Greening must take second place when such very good sorts as Lane's Prince Albert, Blenheim Orange and Wellington are to be had. I would, if restricted to a certain number of Apples, sooner plant Alfriston than Warner's King, for it has three good qualities in that it bears freely, keeps well, and is of large size.—J. NEIGHBOUR, *Copped Hall Gardens, Epping.*

#### PEAR FLEMISH BEAUTY AND ROOT-PRUNING.

THIS Pear, referred to by "J. C.," I think is more common in Scotch than in English gardens. In some districts it does excellently as a standard. Many years ago I took charge of a garden in a Scottish midland county in which some Pears were not worth their room apart from walls. Flemish Beauty was among them—a beautiful pyramid. The fruit trees of every kind were grown by my predecessor in excellent form, and I do not know where such training is to be seen now. Training is not the only art conducive to success. The pyramid referred to was nearly a perfect specimen, about 9 feet high and 7 feet at the base. The fruit ripened badly and was all cracked. I started a "green" hand on to get the soil away from the roots in order to replant the tree above the surrounding level. My assistant (in my absence) made short work of the lifting; he cut off the roots nearly close to the trunk, and thus the tree was easily lifted. My first thought was to burn it, but I relented, and gave the almost rootless stump a chance, replanting on a bed of lime rubbish, over which was placed capital turfy loam, the tree being staked and mulched to keep out frost; this was in November. I looked anxiously to see how this Flemish Beauty behaved the following spring. It did not die, but developed very few leaves. The following year some growth was made, and the dormant buds flowered freely and set a good crop of fruit, and there was no cracking. Every year afterwards, while this tree was under my charge, it produced excellent crops of very fine fruit, deeply bronzed on the side next the sun. The late Mr. Thomas Osborn spent a day among Apples, Pears and Plums, &c., with me once a year as he travelled northwards. He always examined the Flemish Beauty, and told me repeatedly that he never saw the fruit finer in the Fulham district. I have lately received a Pear of this variety to name for a friend; it was from a wall, however, and a good specimen. I would be glad to hear how it behaves in other Scottish gardens. Through the reminder of "J. C." I have ordered two trees for a wall, but have no intention of putting them to the severe test that my young journeyman did the handsome pyramid. When one speaks of root-pruning it should not mean the cutting off ruthlessly of roots that are doing good service to the tree (as is often done), but removing or shortening those which are growing downwards into cold, damp or inert soil, and such as may be causing too much late growth which cannot become matured and does not form fruit buds instead of wood growth. Of course, trees in gardens to remain dwarf require attention at the roots to prevent them from occupying too much space; while in orchards they may be allowed to grow freely.

*Carron, Stirlingshire.*

M. TEMPLE.

## FLOWER GARDEN.

A NEW JAPANESE WINTER CHERRY.  
(*PHYSALIS FRANCHETTI*.)

EVERYBODY knows the bright scarlet fruits of the Winter Cherry, and the wonder is that it is not more widely cultivated for decoration, as

*Physalis Franchetti*, showing full sized fruit.

its brilliant red fruits dry well and make charming winter bouquets along with silvery-fruited Honesty, the plumes of Pampas Grass, the pheasant-tail-like inflorescence of *Apera arundinacea*, the silky Fan Grasses (*Eulalia*), or the heads of the Sea Hollies or *Eryngia*, such as *E. giganteum* (silvery grey) or *E. Olivierianum* and *E. planum*, both of an exquisite steel-blue shade.

One of the most remarkable of all the new introductions from Japan, however, is *P. Franchetti*, which has fruits as large as duck's eggs and of a charming shade of red or orange-vermilion. As seen in the sunlight or by lamp-light the inflated calyces are most brilliant, and being translucent they look exactly like miniature fairy lamps or diminutive Chinese lanterns as seen amid their own soft green leaves or as tastefully arranged along with other suitable green foliage.

This new variety was introduced direct from Japan two years or so ago by Mr. J. Veitch, of Chelsea, and it has been growing and fruiting most luxuriantly this autumn in the nursery trial grounds at Langley, where it has been much admired. The plant likes a deep, rich, sandy soil, well tilled so that its rhizomes can run freely underground, and the result is a little forest of stalks from which droop and glow the little balloon-shaped fruits during the later months of the year. A bed on the Grass devoted to these two varieties of *Physalis*, viz., *P. Franchetti* in the centre and a belt or circle of *P. Alkekengi* around the outside, would form a novel feature in autumn that would not easily be forgotten. In Japan the fruits of both these red-fruited kinds are utilised in the native cookery much as we use the nearly related *Lycopersicum* or Tomato, but it is as decorative plants that they best deserve attention in our northern gardens. Both are perfectly hardy

herbaceous plants, and once well planted, require no further attention except a rich top-dressing over their roots every autumn or winter so as to ensure robust growth and larger fruits.

A large bed or border of these forms of *Physalis* would prove a most novel and interesting feature in all public parks and gardens, and in many private establishments the brilliant fruits would be most acceptable for all kinds of autumnal and winter decorations.

F. W. BURBIDGE.

**Cordyline indivisa in flower.**—Mr. Dorrien Smith has bloomed the true *Cordyline indivisa* in his Tresco garden, and has just sent me part of his home-saved crop of seed. It is the broad-leaved variety we rarely see in greenhouses, leaves 3 feet to 4 feet long, 3 inches to 5 inches wide, olive-green, with fine vermilion-red lines. It grows in the open ground at Tresco Abbey, and when I was there in April it was in flower, and he said it should be photographed. The pendulous flower-spike is quite different from that of all other species of *Cordyline* I know.—F. W. B.

**Belladonna Lily in Norfolk.**—At page 386 J. Crook alludes to the thriving condition of this beautiful Lily at Didlington Hall, and informs us that the plants are growing in a border at some distance from a south wall. This latter fact no doubt accounts for the flourishing condition of this Lily at Didlington, as at Gunton, in the same county, Mr. Allan tried for years to grow it in a similar position, but failed. Several years since, however, he made a narrow border about 18 inches wide and a foot deep close up to the wall of the plant stove. The hot-water pipes inside the stove kept the border always in a warm state. Here the Lily has grown vigorously and bloomed freely, the flower-stems being very strong. When at Blickling last autumn I saw the same plan had been adopted, and Mr. Oecl's plants were blooming freely.—J. C.

## CIMICIFUGA SIMPLEX.

In a recent note on this plant I referred to "Index Kewensis" as an authority for what I said. For the last twenty years I have been trying, with more or less success, to get the nomenclature of hardy garden plants, if not correct, at least consistent in England: and I bought that expensive work—"Index Kewensis," which is only just completed—with a view to help in this direction. I believed that the plan of the work was to give the synonyms or obsolete names of species in italics, whilst the name authorised at Kew is printed in upright square type; and I found the name *Cimicifuga simplex* (Wormsk.) printed in italics and reference made to *C. fetida* (Linn.) printed in square type. I am now told on high authority that *C. simplex* is the correct specific name, and that the "Index Kewensis," is no authority for the correctness of any name, and am referred to a passage in the printed address of the director of Kew to the botanical section of the last meeting of the British Association, which says of "Index Kewensis": "It is a mistake to suppose that it is anything more than the name signifies, or that it expresses any opinion as to the validity of the names themselves." The address goes on to say that there is "one species of *Fimbristylis* of which there are 135 published names under six genera." I conclude that, as far as "Index Kewensis" is concerned, all the 135 are of equal authority, and those who possess the plant may take their choice. Amateurs, I am afraid, generally suppose that synonyms of species are limited to one or two in each, and hardly understand fully the perplexities of botanists. As regards the particular plant about

which I wrote—*C. simplex*—I am told that though it has lost its distinctive simplicity, which De Candolle considered its only special character (we all know that plants thus change their character in cultivation), it is really a distinct species from *C. fetida* (Linn.), with which it was formerly confounded. I make this somewhat long statement because I am really sorry to have questioned a name which was deliberately and purposely retained and authorised at Kew. The authorities at Kew will, I am sure, admit that they have often exhibited in the hardy beds plants under the names sent with the plants by nurserymen, and that those names have often proved incorrect; but it is important to know that names which seem to be preferred and adopted in "Index Kewensis" may also be incorrect, and that the hand list of herbaceous plants alone contains the names which nurserymen and amateurs will be safe in adopting.

Edge Hall, Malpas.

C. WOLLEY-DOD.

P.S.—Some time ago, in a note headed "Telekia formosa," I stated that *Buphthalmum grandiflorum* and *B. salicifolium* appeared to be made synonyms in the "Kew Hand List." The error was mine, and I find the names are printed quite correctly in that list.

## NOTES ON HARDY PLANTS.

**Ostrowskia magnifica.**—The propagation of this plant may be by young growths and by root division. In the case of young growths these appear early and in considerable numbers in the case of old plants. Bare down to the roots and take the growths when 2 inches to 4 inches long with a morsel of the tuber as you would Dahlias, be sure and let the milky sap dry up, then treat as Dahlias. The root-dividing should be done in

*Physalis Franchetti*, cut in half to show berry.

July or August, by which time the plants are turning sear. From the unusual form and character of the roots, their division for increase is exceptional. The roots are very thick, succulent and contorted at sharp angles, and the bulky points, which may either have gone deeply down or come close to the surface, are capable of being taken for the vegetating ends. It is essential to

so deal with the roots that there can be no mistake as to which end before being cut was in the direction of the crown of the parent stock. When I take up the roots I cut the thick roots into pieces the size of one's finger, and mark the upper end at once by a little slit. All the pieces are placed in a dry place until the milk dries up and the cut parts heal, then they are stuck into dry sand in a nipsin fashion with the slit ends upwards, the box placed in a sunny frame and near the glass for the remainder of the summer. The object of this is to secure the roots against decay from damp, to get possibly a little tuft of fibre at the bottom, but chiefly rudimentary crowns. The latter, by the aid of the strong light and long days, soon appear round the exposed cut in the form of wart-like excrescences. These are usually ready to put into 3-inch pots by October, but if the little crowns should become white and soft, pot immediately even if a month earlier, as they otherwise would not be fit for the deep planting in the open, which some might prefer to do rather than pot, and even for potting the too advanced baby crowns would be liable to rot. Such young stock should be kept on the dry side till growth fairly sets in in spring, and even old plants are better for being kept so.

**Primula suffrutescens.**—This rare and curious species, distinct from all others in the way indicated by its name, is, provided you have a fair-sized old plant to operate upon, of quite easy propagation if dealt with at the right time, and that is when growth has stopped and the leaves become firm. Its leaves are of course firm in spring, but that is not the best time, because the new thick roots are not due to push at that season. Autumn (September or October) is the time, and if the cuttings are made with a piece of the stout and almost woody stems, and inserted in sand and kept damp, roots are emitted in two or three weeks. The young plant may either be left in the sand all the winter or potted in a firm compost of chopped turf and sand. It is necessary to keep the collars dry. Pot plants can be easily kept in a cold frame. In the case of plants in the open, cover with a sheet of glass. Those who know the habit of the species will understand the why and wherefore of this, as, owing to the tender and thick succulent stems having been brought artificially close to the surface, rot would ensue if damp lodged at those parts. In the normal state of a mature specimen all the green parts are terminal on woody forked stems. Beyond a doubt mature plants can stand our worst winters. J. Wood.

Woolville, Kirkstall.

**A dwarf Begonia.**—Under the name of *Begonia Vernon* in the "Pierre précieuse" there is an illustration in the French journal *Le Jardin* of an extremely dwarf form of the coloured-leaved variety of *B. semperflorens*. As *B. Vernon* has already attained considerable popularity as a bedding plant, in all probability its dwarf form will be much sought after for the same purpose. In an article accompanying the illustration it is recommended for various purposes, among others that of carpet bedding, so that it must be indeed of low growth. To secure uniformity, it is recommended to propagate it by cuttings or division, as by either method a considerable number may soon be obtained, and it is feared that seedlings will show a certain amount of variability. This dwarf variety is not yet in general cultivation, but is announced for distribution in the spring of 1896.—H. P.

**Leaf sweeping.**—At this season the main task of the gardener consists in sweeping up the fallen leaves from paths and lawns, and the ordinary workman enters upon an almost insensate struggle to restore neatness to Nature. Personally, I like a certain amount of disorder in our gardens in the autumn, for the colour of the leaves, their rustle in the wind, their pleasant odour, and the moral lessons they may teach are all pleasant or sugges-

tions to the contemplative man, who sees with Homer that—

The race of man like leaves on trees is found—  
Now green in youth, now withering on the ground.

Besides, in many cases the natural dead leaf covering is of the greatest use to plants, whose roots are protected by it against their winter trials. Most of the sweepings in shrubberies and the rougher parts of the pleasure ground are not only a waste of labour and money, but actually injurious. At the same time there comes a time, especially in a sudden leaf fall like that of 1895, when the garden proper must have its paths and grass swept. In carrying this process out we are far from having exhausted the resources of civilisation. The gardener enters upon his leafy war with the old broom or besom which has come down to us from antiquity. We have lawn mowers, garden hose, and many other modern mechanical helps, but the tedious and wasteful broom still rules our autumn garden. The purport of this note is to ask why our horticultural instrument makers do not take up the problem of a mechanical leaf sweeper, something on the principle of an enlarged carpet sweeper, with a box behind into which a revolving wire brush in front should brush the leaves. Not only would such a machine save immensely in labour, but it would in small places save the grass plot from an immense amount of injury now annually inflicted upon it by the vicious work of the broom—often a veritable besom of destruction. With a leaf sweeper going its rounds once a week we could still in moderation enjoy our autumn feast of leaves, and at the same time give the gardeners time for their proper work, which incessant leaf sweeping most certainly does not.—J. I. R.

## FERNS.

### GOLD AND SILVER GYMNORAMMAS.

WHILE there are two or three *Adiantums* and a few *Notholaenas* and *Cheilanthes* with foliage either golden or silvery on their under side, the *Gymnogrammas* are, according to garden classification, much more numerous and offer also a much greater variety of colours. Botanically speaking, nearly all the Gold and Silver *Gymnogrammas* in cultivation are represented by two species only, for Hooker and Baker in their "Synopsis Filicum" bring nearly all the forms now found in gardens under the denomination of varieties of two species only—*G. calomelanos*, a West Indian species, and *G. tartarea*, a native of Tropical America. According to Baker's theory, these two species, which in their natural state have their foliage of a silvery nature, are very variable, including as they do a variety of forms which are connected by very gradual shades of colour of the powder with which their under side is covered, and which forms their most attractive as also their most distinctive character. Whether such plants as *G. chrysophylla* and *G. Massoni*, for instance, whose fronds have their under side respectively of a bright and of a deep yellow, are simply varietal forms or species proper is of little import so far as garden purposes are considered, for they are from a decorative point of view totally distinct and essentially different, although similar in habit and in botanical characters to the typical species with which they are said to be so closely connected, and, wrongly or rightly, they are usually considered as distinct species. Sometimes, in fact, plants are found which bear fronds suffused with white and yellow powder at the same time. This form of dimorphism in colours may frequently be observed in forms derived from the *calomelanos* type, which also sometimes produce fronds provided with the usual coating on one half, whereas the other

portion is completely destitute of the coloured powder. Such instances, however, can only be regarded as curiosities. The same remark is also applicable to the forms with forked or crested fronds, which under cultivation *Gymnogrammas* have a peculiar tendency to produce; of these, *G. Parsonsi* and *G. Wettenthaliana* are excellent examples.

The genus *Gymnogramma*, so far as the gold and silver representatives of it are concerned, is almost exclusively composed of plants indigenous to hot climates, with foliage more or less finely divided, and requiring under cultivation a minimum temperature of 55° in winter. It may be safely said that all *Gymnogrammas* are very ornamental, and that the majority of them may be grown with success in hanging baskets, in which position they show the beautiful colours of their foliage to perfection. Wherever it is practicable this way of cultivating them is really the most suitable, as these plants are fond of light and also of an atmosphere drier than that found in the ordinary fernery or warm plant house. Owing to their great dimensions and robust growth, some kinds, however, are more successfully grown in pots. As a general rule and with few exceptions, *Gymnogrammas* should be potted firmly in a material of a light and permeable nature made up of two parts of fibrous peat, one part of leaf-mould, or if this is not readily procurable, the same quantity of chopped *Sphagnum Moss* may be substituted, and one part of silver sand. As they not only suffer from the effects of watering overhead, but as under such circumstances they present a wretched appearance through the white or yellow meal being easily displaced by the slightest sprinkling of water over their foliage, these plants when grown in pots should not be mixed among other Ferns, but be kept by themselves and out of reach of the water from the syringe. Although particularly fond of a dry atmosphere, *Gymnogrammas* suffer if water is not freely administered at the roots, and lax treatment in this respect is often fatal to them, or, at all events, accounts for the poor state and diminutive size in which one frequently sees them in general collections, as they invariably take months to recover from one day's drought when they are not killed outright by it. They grow very well and get a much better colour if kept without, or with only very light shading, the light never being too much for them, provided they have been accustomed to it from the first, and that good ventilation is provided in the house or part of the house devoted to their culture. The propagation of *Gymnogrammas* is readily effected by means of their spores, which are produced in great abundance, even in young plants, and which germinate freely and make handsome specimens during the course of one year.

The following are the most distinct and the most beautiful species and varieties known in gardens, with foliage either golden or silvery underneath:—

#### GOLDEN VARIETIES.

**G. ALSTONIE.**—This remarkably handsome plant, of garden origin, appears to be a variety of *G. chrysophylla*, which it resembles in general aspect. The peculiarity, which greatly enhances the beauty of the plant and which renders it distinct from any other form, is the way in which the greater part of its leaflets is turned upwards and gracefully incurved, making the upper side of the fronds appear as if dotted all over with little golden globules. It is also an exceedingly good grower and reproduces itself fairly true from spores.

**G. CHRYSOPHYLLA.**—This beautifully coloured plant is a native of South America and the West Indies, being found abundantly in the

islands of Martinique and San Domingo. Its handsome fronds, produced in great abundance from a closely-set crown, are usually from 18 inches to 24 inches long, sometimes longer, including the stout, round, chestnut-brown stalks on which they are borne, and which keep them in a nearly erect position, giving the whole plant the appearance of a huge golden shuttlecock, and showing the bright yellow colour of their under side to great advantage. In reference to this plant, E. J. Lowe, in his extensive work "Ferns British and Exotic," vol. i., p. 3, says: "Of all the Ferns cultivated in Great Britain, perhaps no species is so universally admired as *Gymnogramma chrysophylla*, the king of the Gold Ferns."

*G. DECOMPOSITA*.—Although it has been reported and described as having been raised in the late Mr. Gair's collection in Scotland, this strong-

pinnae, the basal pair being the longest: these pinnae are divided into small pinnules, which are again split into several minute finger-like lobes, giving the whole plant a finely-dissected appearance. It may be noted here that this lovely plant reproduces itself freely and true from spores.

*G. GRANDICEPS*.—This is perhaps one of the most striking of all the known Gold Ferns. Its fronds, which sometimes reach 18 inches in length, including their stalks, are spear-shaped and three times divided to the midrib; their distinctive character, however, lies in the broadly tasselled nature of the drooping apex. The underside is densely coated with a powder of a pale yellow colour, and the segments, instead of being rounded or blunt as usual, are conspicuously pointed. This beautiful form is best propagated by the division of the crowns, although it is a slow process, as

is a native of Guadaloupe, one of the largest of the Caribbee Islands. On account of its slender habit and its light colour, the general appearance of this form is very much that of a plant half way between *G. sulphurea* and *G. chrysophylla*, as its fronds are much more slender and their leaflets more finely cut than those of the latter species, while their under side is of a much darker colour than that of the fronds of *G. sulphurea*.

*G. MARTENSI*.—E. J. Lowe states that Link considered this Fern, which he gives simply as a native of South America, as a hybrid variety between *G. calomelanos* and *G. chrysophylla*; also that under similar cultivation the latter species is less in size, more triangular in form, has the pinnules more expanded, and is not so sharply pointed at the extremity of the pinnae. The fronds of *G. Martensi* are 18 inches to 24 inches long,

*Gymnogramma Lauchiana* at Warley Place. From a photograph by Miss E. A. Willmott.

growing species, which by its habit as also by the nature of its fronds, which are fully 24 inches long and 12 inches broad, suggests a natural hybrid between the lovely *G. Pearcei* and the golden *G. chrysophylla*, is given by Baker as a species "probably Andine," and by Nicholson as a "native of South America, introduced in 1873." Whether a species or a variety, *G. decomposita* is a remarkably handsome and totally distinct Fern with somewhat the habit of *G. pulchella*, but when in a young state much more finely divided and scantily furnished with powder. This powder is white or nearly so, but as the plant gets older it becomes of a bright yellow colour and covers the stalks, but seldom extends to the leafy portion of the fronds, in this respect resembling the finely-cut *G. Pearcei*. Its fronds are four times divided nearly to the midrib and furnished with triangular

seedlings seldom reproduce the plant in its true characters.

*G. LAUCHEANA*.—The fronds of this beautiful and symmetrical form, of dense habit and smaller dimensions than *G. chrysophylla*, from which species it is thought to be issue, are quite triangular in shape, and are borne on stout stalks only sufficiently long to give them a gracefully arching appearance. They seldom measure more than 18 inches long, and their under side is of a particularly bright and uniform golden colour, which increases in depth as the fronds become older. This very variable variety has produced several forms, and notably the one called *gigantica*, with fronds much longer, but not triangular.

*G. L'HERMINIERI*.—According to Lowe, this uncommon Gold Fern, which undoubtedly is the prettiest of the many light forms of *G. chrysophylla*,

twice divided to the midrib and furnished with spear-shaped leaflets, the segments of which are conspicuously and sharply toothed; the colour of their upper surface is a dull yellowish-green, whilst beneath they are profusely covered with a rich deep yellow powder.

*G. TRIANGULARIS*.—This is commonly known as the Californian Gold Fern, being, according to Eaton, very common on rocky hills nearly throughout California, extending northward to Oregon and southward to Ecuador. It is a very pretty and thoroughly distinct species with elegant triangular little fronds about 3 inches each way independent of their slender, dark chestnut-brown, glossy stalks 6 inches to 12 inches long and produced in tufts. The fronds are of a somewhat leathery texture, smooth, and of a dark green colour on their upper surface, while their

under side is densely coated with a powder which varies from deep orange to sulphur colour, and occasionally even to white. The temperature of a cool greenhouse suits it best all the year round.

**G. MASSONI.**—As a Gold Fern, and also as a decorative plant, this *Gymnogramma*, the origin of which is apparently unknown, is very remarkable on account of the length of its fronds, which are spear-shaped, handsomely golden beneath, somewhat loose, and of a pendulous habit, making it an excellent plant for hanging baskets of large dimensions.

**G. MAYI.**—In habit as well as in general aspect this variety, of garden origin, is very similar to the better-known *G. peruviana argyrophylla*, from which no doubt it is issue. It is, however, of a more robust constitution, and the farinose powder with which its fronds, more massive than those of the above-named species, are covered on both surfaces, instead of being a pure white, is of a light sulphur-yellow, and is also noticeable, though in less quantity, on the entire surface of the stalks.

**G. COHRACEA.**—This Gold Fern, which is by Baker considered as a variety of *G. tartarea*, from which it differs essentially through the bright yellow colour of the under side of its fronds, is a native of Peru, and probably the most accommodating of all the *Gymnogrammas* as regards temperature, as it succeeds equally well in a greenhouse or in the stove. Its fronds, which are also produced in greater abundance than those of most other species or varieties, have their pinnae very regular, closely set, and only the lowest ones are distinctly toothed; they are of a bright shining green above, which forms a very pleasing contrast with the yellow colour of their under side.

**G. PARSONSI.**—This beautifully crested form, of garden origin, is of comparatively dwarf dimensions, its fronds, densely coated with bright golden powder underneath, seldom exceeding 12 inches in length. They are of upright habit and particularly handsome and interesting, through their extremities being formed into a broad, but finely divided tassel, while each pinna terminates in a crest, becoming smaller as it reaches towards the base of the fronds. It should be remarked here that it is very liable to damping off, through accumulation of moisture in the tassels and crests of the fronds during the winter, when it must be kept in a particularly dry place and as close to the light as possible. It is undoubtedly the most popular of the crested forms of golden *Gymnogrammas* known, because it is easily reproduced from spores, although it is somewhat variable in its mode of cristation, producing plants with fronds whose crests are of a more or less flattened nature; whereas those of *G. Parsonsi* type form a regular golden tassel at their extremity.

**G. WETTENHALLIANA.**—This very distinct variety is of garden origin. In good varieties the fronds, besides having their extremities ornamented by a large corymb, bear also dense crests at the points of all their pinnae. The colour of their under sides is pale sulphur or lemon, sometimes paler still, as seedlings of it vary very much in colour and also in cristation.

**G. SULPHUREA.**—A pretty, small-growing species, native of the West Indies, and one which is easily distinguished by the delicate cutting of its fronds, as also by their soft texture and their decidedly spear shape. They seldom exceed 9 inches in length and 3 inches in breadth. The pinnules are pale green above and profusely covered beneath with a brilliant sulphur-yellow farinose powder, of which there is also an occasional sprinkling on their upper surface. Unfortunately, this pretty little species is more difficult than other *Gymnogrammas* to grow from one year to another, and should be kept during the winter months as close to the light as possible and comparatively dry, or at least "on the dry side" at the roots.

**G. VEITCHI.**—A beautiful variety of garden origin, considered as being a hybrid between *G. chrysophylla* and *G. Pearcei robusta*. It is undoubtedly one of the handsomest *Gymnogrammas* known, having the finest cut pinnules of all the

golden species and varieties known; it is also the most robust in habit and of a very light and graceful aspect. Its tufted fronds, which attain 3 feet to 4 feet in length, are elegantly arching all round; their stalks, somewhat slender and of a chestnut-brown colour, are covered with sulphur-yellow powder, which extends to their leafy portion. The pinnules are cut into segments so fine as to impart to the fronds a lace-like aspect.

**G. CALOMELANOS.**—This very handsome and extremely variable species, native of the West Indies and also of the Tropical West African Islands, is one of the largest-growing kinds of gold and silver Ferns. Its fronds, abundantly produced and bending outwards, often measure 2 feet to 3 feet in length and 1 foot in breadth. Their spear-shaped leaflets, often cut down quite to the midrib, are closely set and divided into distinct toothed pinnules of a somewhat leathery texture, dull green on their upper surface, but entirely covered underneath with creamy white farinose powder.

#### SILVER VARIETIES.

**GYMNOGRAMMA ARGENTEA.**—A very pretty species, of dwarf habit, with elegant little fronds borne on slender, glossy stalks 3 inches to 6 inches long and of a chestnut-brown colour. Their leafy portion, divided into leaflets 3 inches to 4 inches long and 2 inches broad, is of a soft, papery texture. Their under side is coated with a white powder, while the spore masses are of a peculiar pale brown colour. It is a native of Natal and the Mascarene Islands and a very rare plant. A variety of it, named *G. aurea*, has its fronds coated with yellow powder; this is found in Madagascar, Bourbon and Angola.

**G. PEARCEI.**—This exceedingly elegant species, native of Peru, is entirely distinct from all other *Gymnogrammas*. Its beautiful and most elegant fronds are more finely divided than those of any other species or variety. The fronds, which are borne on glossy stalks 6 in. to 9 in. long and of a bright chestnut-brown colour, are of a thin, papery texture and of a dark shining green colour above, while the under side is sparingly dusted with white powder, which extends along the stalks and to the crown of the plant. *G. Pearcei* has, unfortunately, become very scarce in collections.

**G. PEARCEI ROBUSTA.**—Like the typical species, of which it is an accidental seedling of comparatively recent production, this variety has somewhat triangular-shaped fronds of a dark green colour and very finely cut, but these are narrower at the base and more elongated towards the summit; in other respects it is larger in all its parts and of a much more robust constitution. The under side of the fronds, the lower portion of their stalks, and the crown itself are covered with white powder. It also differs from the typical plant, which usually has but one single crown, in forming, even when in a young state, a tuft of crowns, from which many stalks arise, giving the plant a denser habit and the appearance of being better furnished than the typical species. This variety has only recently been known to produce spores; its propagation, therefore, is limited to the division of the crowns, which operation is safely performed in the early part of the year.

**G. PERUVIANA ARGYROPHYLLA.**—This is undoubtedly the best and most distinct of all the known *Gymnogrammas* with silvery foliage, and differs from most other known kinds by having its massive fronds heavily dusted on their upper as well as on their under surface with snow-white powder. Its splendid fronds, 24 inches to 30 inches long and about 15 inches in their broader part, are comparatively broad and blunt. It is of excellent habit and of remarkably good constitution, and on a specimen in good health the thickness of the white powder on the upper surface of its fronds is such that nearly all traces of green have disappeared and the plant presents a glaucous or bluish white appearance; but it should be borne in mind that on that account it is more likely than any other sort to suffer should its foliage get wetted over. It possesses the property of reproducing itself true from spores.

**G. SCHIZOPHYLLA.**—A very distinct species, native of Jamaica, which, though but slightly provided with white powder, is, however, one of the most attractive of Ferns through its elegant contour, its graceful habit, the delicate cutting and the pleasing colour of its foliage. Its delicate-looking fronds, which are produced invariably from a single crown, are borne on slender stalks of a reddish brown hue; they are from 18 inches to 24 inches long, about 6 inches broad, and are elegantly arched. It will thus be seen that it is one of the best and prettiest Ferns adapted for growing in hanging baskets of medium dimensions. This species also differs from all other known *Gymnogrammas* in its being prolific, its fronds being forked towards their extremity where a young plant is produced; this roots very freely when pegged down on a mixture of peat, chopped Sphagnum and sand in about equal proportions.

**G. S. GLORIOSA.**—This beautiful variety, of garden origin, is of much more robust habit than the typical plant, and produces from a central crown fronds of much larger dimensions and of a peculiarly feathery nature. It reproduces itself true from spores, which are abundantly produced, and also from young plants which are found growing not only at the extremity of the fronds, as in the species, but even at the end of each leaflet.

**G. TARTAREA.**—This very distinct and deservedly popular species, which is often found in gardens here and invariably on the Continent under the name of *G. dealbata*, is a native of Tropical America and a thoroughly distinct plant. It is a strong grower, its fronds measuring 24 inches to 30 inches long and sometimes 12 inches broad, borne on firm stalks of a dark chestnut-brown colour, and 6 inches to 12 inches long. The fronds are of a dull green colour on their upper surface, but entirely covered on their under side with a thick coating of snowy white farinose powder, with which the abundantly produced and conspicuously black spore masses form a very striking contrast. S. G.

#### DECIDUOUS FERNS.

Among the stove and greenhouse Ferns, few lose their fronds entirely at any period of the year, yet among those which do so there are some very desirable species. It not unfrequently happens that these get lost during the dormant period, sometimes through improper treatment, and I have known of several instances where they have been thrown away as dead by those not acquainted with their habits.

In the culture of all the deciduous Ferns, it is desirable to give them such treatment as will induce them to go to rest in the autumn; they will then have more strength to start early in the year. If grown under the ordinary treatment given to evergreen Ferns, they will struggle on nearly through the winter, but will only make weakly fronds; the rhizomes or crowns will be weak, and consequently very late in the spring before they make a start.

While it is desirable to gradually dry off the plants in the autumn, they should not be kept too dry after the fronds have dried off. The British Ferns ripen off their fronds in the early autumn when the ground is very dry, but later on, after they are quite dormant, they get an excess of moisture rather than otherwise. Such conditions no doubt apply more or less to deciduous exotic Ferns, though I should not recommend giving more moisture than would be sufficient to keep the roots from suffering, especially when grown in pots. When planted out they will generally derive sufficient moisture from the soil, but in elevated positions or where the soil does dry up, water should be given occasionally. I like, where possible, to leave the old fronds on after they have ripened off, as they help to protect the crowns of the plants, besides indicating what the plants are.

The *Adiantums* are among the most difficult to keep. *A. lunulatum* is a pretty plant for growing in baskets, and, except that it is deciduous, is a far more desirable Fern than *A. dolabriforme*. *A. palmatum* is another very elegant deciduous Fern. This is inclined to keep growing late in the winter if not checked by being kept cool and dry for a time. *A. speciosum*, which under good treatment makes very large fronds, requires great care both in keeping the plants while dormant and in growing them. It is not often that good specimens are seen, though it is, when well grown, a most elegant Fern. The deciduous *Davallias* give less trouble. *D. Mariesi*, which is one of the best, loses all its fronds annually, but the new fronds start away almost before the old ones have ripened off. There is a very pretty crested form of this. *D. bullata* is another good species, the rhizomes of which are attractive when destitute of fronds. *D. (Leucostegia) immersa* makes a very fine basket Fern. *D. (Acrophorus) pulchra* is another deserving of notice. Of *Nephrolepis* there are two very desirable varieties which must be included in this list; they are *N. pluma* and *N. Bausei*, the latter, I believe, a variety of the former. *Lygodium japonicum* (usually known in gardens as *L. scandens*), though it may be kept green throughout the year, makes more satisfactory growth when treated as deciduous.

#### NORTH AMERICAN VARIETIES.

Among these there are some very beautiful deciduous Ferns. *Adiantum pedatum*, though hardy, is well worth a place in the intermediate house. Newly-imported plants will die off early in the autumn, and if started in warmth early in the year will soon make fine plants. I believe this fine Fern is grown much more extensively on the Continent than in this country. *Onclea sensibilis* is another very desirable Fern. Of *Osmundas*, there are three which should be included in this list; they are *O. cinnamomea*, *O. Claytoniana* and *O. gracilis*. The last closely resembles *O. palustris*. *Struthiopteris pennsylvanica* may also be included. Although these North American Ferns are quite hardy, they succeed best when grown in a cool house, for when fully exposed they begin to grow early in the year and often get cut back by late frosts. Good loamy compost will suit all those referred to; started in a little warmth and given a little liquid manure, they make very fine fronds. The great beauty of all the deciduous Ferns is that they have such a fresh, green appearance, and make nice specimens with little trouble. A. HEMSLEY.

#### A GARDEN STREAMLET.

It is difficult to over-estimate the value of running water in the flower garden, however inconsiderable its volume. Effects are possible on the slope of even a tinkling rill that will vie in simple loveliness with any of the varied beauties of a wide pleasaunce. I know a garden in which naturally running water has been utilised with great success. Formerly the runnel, entering from under an ivied wall, crossed the garden by a subterranean channel, flowing unseen and unheard below the flowers, eventually passing out beneath the opposite wall and high road on its course to join a larger stream in the meadow beyond. There being a fair slope from side to side of the garden, it was decided to form a channel on the surface of the ground, and to endeavour to turn the streamlet into it. After some little trouble, the water being loth to leave its underground passage, this was accomplished, and the results

have been all that could be wished. The little rivulet now gurgles into the garden through a hole in the Ivy-clad wall, turns with a swirl to the right, and, skirting a rockery at the wall's foot, in which *Osmunda* and *Lady Fern*, *Hart's-tongue* and *Male Ferns*, *Asplenium* and *Ceterach* flourish, interspersed with *Myosotis* and *Primroses*, *Cyclamens* and creeping *Forget-me-not*, *Saxifrages*, *Sedums* and white *Pinks*, flows for a few yards between it and a narrow path, the rough edging stones of which are fringed with a margin of Ferns and yellow *Fumitory*. Then, disappearing from view, it slants beneath the rough poles of a level bridge, coming to light again by a clump of Japanese *Iris*, and, curving away from the path beneath an overhanging lace-work of *London Pride*, passes pendulous turquoise heads of the Virginian *Cowslip* (*Mertensia*), patches of *Dropwort* (*Spiraea filipendula*) and the feathery inflorescence of *Spiraea japonica*, *S. palmata* and *S. venusta*, while in the background stands, on one side, a colony of the Golden-rayed *Lily of Japan* (*L. auratum*) overshadowed by the broad leaves of a lofty Palm-like *Aralia spinosa*, and rising from out a breadth of hybrid *Aquilegias*, their mingled blossoms a dream of harmonious colouring—reds and yellows, faint pearl-greys and sulphurs, dark purples and dead whites, to be succeeded later in the season by a backing of *Starworts*, perennial sunflowers and *Cactus Dahlias*. On the other side are clumps of *Tradescantia virginica*, *Oenothera Youngi*, and the tall scarlet *Lychnis chalcodonia* backed by a large plant of the *Lyre Flower* (*Dicentra spectabilis*), *Hedychium* and brilliant-flowered *Cannas*, behind which a large bush of *Spiraea Lindleyana* spreads white panicles of bloom above its graceful leafage, and the partnership of the New Zealand Reed (*Arundo conspicua*) with *Pampas Grass* (*Gynerium*) extends the season of the downy feather plumes from July until late November. By a bushy shrub of variegated *Box*, through which twice the growths of *Tropaeolum speciosum*, *T. canariense* and *T. tuberosum* that grow on an old tree-bole and drape the stiff *Box* sprays with vivid trails of scarlet, orange and yellow, the runnel suddenly swerves, and, hurrying past the white trumpets of the Bermuda Lilies, takes a 3-foot leap between overreaching *Lady Ferns* and bounteous clusters of *Poet's Narcissi* into the Moss-grown and Ivy-wreathed semicircle of an old dipping well, falling with ceaseless song into the shallow pool beneath. In the spring the voice of the water is full and varied. It lifts the joy of the budding year, telling of the blue shimmer of wild *Hyacinths* about the grey *Beech* trunks on the hill that slopes above its source, of the scent of *Primrose* and white *Violet*, with which its eddies have tarried for a moment to whisper, of the unfolding of the curled Fern fronds, of the mantle of bright gold spread by the *Marsh Marigolds* in the water meadow and of the coming of the swallows; and, as it sings, ever and anon a scattering of pearl-bright drops falls upon hanging leaves and bending blossoms that nod their heads and bend yet lower to listen to the spring song of the stream. In the torrid summer heat the music of the fall is pitched in a minor key; its low refrain is unnoticed by the listless drooping leaves, unheard by the Lilies, that hold aloft their pure white chalice and await the hour when they shall be free to yield their fragrance to the dewy kisses of their lover—the evening breeze. The water dreams, and in its dreaming croons to itself of the luminous, jewelled eyes and iridescent gossamer pinions of the dragon-fly that flashed a momentary brilliance through the mazes of the tall *Foxgloves*; of the butterfly that with outspread, peacock-eyed

wings, rested on the overhanging, shell-pink *Dog Roses* and of the water Reeds that retarded its languid flow. In the drenching, equinoctial days the voice of the cascade becomes a sonorous, hoarse monotone, its music fraught with memories of submerged, straining *Flag* leaves, of swaying tangles of scarlet-berried *Bryony* and of the drowned "gold of the ruined woodlands." Its turbid flood is encumbered with strange flotsam, hurrying ever on; the frail blue shallops of broken thrushes' eggs, black, sodden *Chestnuts*, lichened twigs, and fungus-covered bark—waifs and strays that have lingered long in sedgy nooks and quiet backwaters for the coming of the autumnal rains to bear them seaward. In the winter when the drifted snow lies deep above its upper course, the rill leaps out from its tunnelling into the light of a white world and falls amidst a setting of bright, keen icicle spears into the pool below, now black by the contrast of the glistening purity of its surroundings.

At the foot of the fall the path again approaches the streamlet, 2 feet of sloping bank intervening between it and the water. On the opposite side, just out of reach of the sprinkling of the cascade, stands a collection of tall *Iris*es—*ochroleuca*, sometimes known as *gigantea*, *aurea*, and *Monnieri*, which bear 5-foot high scapes of showy blossoms, white, golden, and yellow. Further down are other *Iris*es, great tufts of *Iris Kämpferi*, both double and single, planted in specially prepared soil, light and rich; the great sweet-scented lavender *Flag* (*I. pallida*), *I. sibirica*, with its narrow grassy foliage and white and veined blue flowers.

Interspersed with the *Iris*es are herbaceous *Spiraeas*, *Day Lilies*, the fragrant yellow *H. flava* and the variegated *H. Kwanso*, brilliant scarlet *Lobelia cardinalis* with an undergrowth of white *Violas*, deep blue *Salvia patens*, early and late *Gladioli*, *Doronicums*, and masses of white and crimson *Phloxes*; whilst above the handsome foliage of *Gunnera scabra* and *Acanthus* lofty spires of the *Cape Hyacinth* (*Galtonia candicans*) droop white bells, tall *Campanulas* bloom, *Delphiniums* rear their azure heads, *Flame Flowers* (*Kniphofia*) orange-scarlet spears glow, and the giant Himalayan *Lily* (*L. giganteum*) diffuses the vanilla-scented perfume of its pendent blossoms. In the background every passing breeze stirs the pinnate leaves on the graceful arching shoots of the *Bamboos* (*B. aurea* and *viridi-glaucescens*), and the shining deeply-cut foliage of *Aralia* (*Fatsia japonica*) throws into relief its quaint inflorescence. On the narrow bank between path and stream are clumps of *Narcissi*, spring and summer *Snowflakes*, English and Spanish *Iris*es, the winter-blooming *Iris stylosa*, *Montbretia crocosmiaeflora*, and *Schizostylis coccinea* mingled with *Forget-me-not*, *Woodruff*, the Mexican *Daisy* (*Erigeron mucronatus*), and *Omphalodes*. Turning again sharply by a large plant of the blue African *Lily* (*Agapanthus umbellatus*), the rivulet skirts a 9-foot high clump of the Great Reed (*Arundo donax*) and takes a second plunge, this time between graceful trails of *Muhlenbeckia complexa* into a hollow of rockwork, the upper spaces of which are overgrown with *Saxifrages* and *Sedums*, *Campanulas* and *Aubrietias*, *Gentianella*, *Plumbago* *Larpenae*, *Yuccas*, *Linum flavum*, the blue *Apennine Windflower*, *Arabis* and *Alyssum*, the lower level being the home of the variegated *Water Flag*, whose striped sword leaves rise from the gold and crimson of *Mimulus* blossoms and the pale blue of the *Water Forget-me-not*. In this hollow the streamlet, disappearing beneath a veil of *Muhlenbeckia*, leaves the gar-

den, having afforded during almost every season of the year, in its course of under 50 yards, evidence of the beautiful effects obtainable by the appreciative association of flowers and foliage with running water. S. W. F.

## KITCHEN GARDEN.

### LETTUCES IN WINTER.

I SHOULD be glad if any of your numerous readers who have been successful with Lettuce during the winter months could advise me of any means whereby crisp, well-grown Cos Lettuce could be had during the month of February. My employer tells me he can get beautiful Lettuces at Covent Garden during that month.—YOUNG GARDENER.

\* \* \* Much, but not all of the excellent Lettuce that finds its way to Covent Garden Market and from thence to provincial towns during the winter is undoubtedly imported from France. Cloches, or large bell-glasses, are largely used by the French growers, and of late years these have also become part of the stock-in-trade of the more enterprising classes of market gardeners round London, Bristol, Bath, and elsewhere. Although "Young Gardener's" employer seems to prefer Cos Lettuces, we may reasonably presume he would not be averse to well-grown Cabbage Lettuce as well, and in order to have a good and continuous winter supply of both, several dozen of these cloches ought to be provided. Each of these is capable of holding one central plant of a Cos variety and five plants of a Cabbage Lettuce around it. It is not too late to commence the French method of culture now, always provided "Young Gardener" has a number of late-raised Hicks' Hardy White Cos or Black-seeded Brown Cos, and either All the Year Round or, better still, Commodore Nutt and Early Paris Market Cabbage Lettuces just large enough for transplanting. A sheltered border with a good slope to the south and the soil moderately light and rich is the best position to select for the cloches, and fill these in this way: Arrange a row of cloches closely together across one end of the border to be filled, press these into the soil and plant inside the rings so formed. If one plant of Cos variety is placed in the centre, ten plants of a Cabbage variety may be arranged around it 3 inches or so from the ring, one half of these being cut out for use before they have actually hearted in. In this way one or several lines of cloches can be filled, a good succession being afforded from sowings made at intervals of a fortnight, or rather more, during August and September, those raised in October not hearting till early in the spring. Much naturally depends upon the weather experienced and the locality itself, and that is why it is unwise to name any particular date for sowing. Once the cloches are placed over the plants they should be kept closed down, as it will be found that abundance of light will keep the plants sturdy enough, and they will continue to make good progress in all but very frosty weather. Cover with either straw litter or double coverings of mats whenever severe frosts are imminent, but at all other times admit as much light and sunshine as possible. The Cabbage Lettuces will be the first fit for use, and the central plant will improve considerably after their removal, all being very crisp and tender and with a fair amount of blanched centre.

Good Lettuces could also be cut from pits and frames throughout the winter, but these should

have a sharp slope to the south and not be too limited in extent. It is useless to try to keep nearly or quite fully grown plants after mid-winter—at least, such is my experience, and if, therefore, good well-grown Lettuce is wanted in February the start should be made at once with strong plants prepared in the open ground. Form a hotbed of leaves and manure, trampling these together as firmly as possible with a view to having a gentle, lasting heat rather than a strong bottom-heat that will not last long. Cover with a thin layer of short manure, and on this place 6 inches of rich loamy soil. Too often Lettuce and late Endive are planted in poor soil and kept dry at the roots, whereas they should have moderately rich, though not very heavy soil and be kept constantly moist at the roots, these promoting a steady, yet strong growth. When planting Lettuces, let the earlier hearting Cabbage varieties alternate with Cos varieties, the latter having time to improve after the former are cut. Arrange the Cos varieties 8 inches apart in rows 12 inches asunder, the Cabbage varieties being planted rather more thickly in the alternating rows—that is to say, midway between the rows of Cos Lettuce. Keep the frames or pits close till the plants are well established, and give little or no air during the winter, unless it is found necessary to check a spindly growth consequent upon too little sunshine and light reaching them. If a "Young Gardener" has no plants suitable for starting into growth in frames, he cannot expect to have Cos Lettuce fit to cut in February next, but should the winter prove to be somewhat mild and open, it might be possible to have really good Cabbage Lettuce early in March, the plants for this crop being raised from seed sown now. Either Golden Queen or Early Paris Market are suitable for the purpose, both forcing admirably and by many would be preferred to Cos Lettuce. Sow the seed thinly in pans, place in heat to germinate, and before the plants become drawn, raise them well up to the glass in rather less heat than formerly. On no account raise two hundred plants when one hundred would be ample unless more than one pan or box is used, the thinly-raised plants not requiring to be pricked out before they are placed where they are to attain their full size. Prepare a gentle hotbed in a frame or pit much as already advised, and by the time the plants are large enough to move, allowing them to become drawn and weakly being a very bad start. Dibble out somewhat thickly, so as to be able to cut out every other one for use before they are large. When well looked after in the way of extra protection in cold weather and watering, growth is fairly rapid, and when fully grown these forced Cabbage Lettuces are so very tender as to require to be very carefully packed in boxes when sent to the town house. Those I have forced in frames have been considered superior to any Lettuces cut during the rest of the season, but I do not quite agree with such a statement, having a predilection for perfectly blanched hearts of the Brown Cos varieties.—W. JGGULDEN.

**Large Beet.**—The season has evidently been at fault as regards garden Beet, for coarse roots, as noted by "G. W. S.," seem pretty general this year, and I have noticed many plots containing very large roots. On one large plot in particular the roots have reached such a size as to be entirely useless for cooking, and they will be given to the cattle. The strain is not at fault, as the seed was carefully saved at home from selected roots of a variety which has been grown in the same garden for very many years, and which has never before been coarse. Seed is sown about the first week in May. My own roots of the same

variety are but little bigger than usual, as the soil is neither so deep nor so rich. I grow besides this a good breadth of Dell's Crimson, which I sow in the kitchen garden, transplanting the thinnings from there to the flower garden, so that I always have a fair batch left behind. I find this a better plan than sowing where the decorative plants are to be grown, as birds are not so troublesome, and transplanting being all done about the same time, there is less chance of gaps, nothing transplanting so easily as Beet if caught at the right time.—J. C. TALLACK.

**Cauliflowers.**—The sharp frosts of a few weeks since practically led to the disappearance of Autumn Giant Cauliflowers from the shops for a time, but a return to open, and for some time distinctly mild, weather enabled late plants to complete heading, so that just recently again Cauliflowers have been for the season fairly abundant. This fact shows how important it is not only to plant for autumn supplies abundantly, but also successionally. To be content with the products of one sowing for autumn use exhibits little desire to cater for a season's needs in the fullest way. Seed is cheap and the ground needed for a sowing very small: therefore to have enough in succession and to spare it is wise to sow in March, April and May, planting out as plants and circumstances will admit, but always making one late planting at least, so as to have some to head in during December, when it so frequently happens we have a mild time. What with Snowball, Early Mammoth, Magnum Bonum, King of the Cauliflowers and Autumn Giant, some not materially differing from others, we have the finest conceivable material for the keeping up of a supply over a long season. Snowball sown in January and pricked out into a frame, then transferred to an open, warm border under hand-lights, gives, if not large, at least perfect heads in May and June, whilst sowings in February and March of the larger-headed varieties carry on the succession till heads from plants raised outdoors are ready for cutting. Generally, we plant these large Cauliflowers in soil that is too rich, because for some purposes big heads are desired. Ordinarily, however, they are better in less rich and firmer soil, planted too more closely, getting up to Christmas more heads if they be of less dimensions.—A. D.

## GARDEN FLORA.

### PLATE 1043.

#### CALOCHORTUS LUTEUS CONCOLOR.

(WITH A COLOURED PLATE.\*)

THE Calochorti have been brought into prominent notice of late, and are likely to receive more attention in gardens, since it has been proved that they can be successfully grown in the open ground, and, given the right conditions, with much more success than when they are coddled up in pots and frames. There is no need, however, now to refer to the family extensively or to give details of culture, several articles having been devoted to these flowers and their requirements both in the current and two previous volumes of THE GARDEN.

The variety here figured is another most noteworthy addition to the family, and for its introduction we are indebted to Messrs. R. Wallace and Co., of Colchester, who have made a speciality of these fascinating flowers. *C. luteus* is a pretty species that gives a welcome change of colour in comparison with the many forms of *C. venustus*, its flowers being of a clear lemon-yellow, spotted with brownish red at the base. The variety here figured has been placed by Mr. Baker under *C. luteus*, with the distinguishing

\* Drawn for THE GARDEN by H. G. Moon in Messrs. Wallace's nursery at Colchester. Lithographed and printed by Guillaume Severeyns.

name of concolor. It obtained an award of merit at the Drill Hall on July 13 of this year, and we saw it flowering in the nursery at Colchester, where it was very conspicuous previous to the above-mentioned date. In growth it is very sturdy, its shoots standing up boldly erect, and although little more than 1 foot in height, they are freely branched and bear great numbers of flowers. Those shown in the accompanying plate are secondary flowers and not so large as the earlier blooms we saw. The colour is a rich buttercup-yellow, the petals glistening in the sun as if polished, and slightly marked with chestnut-red at the base. Those who want to confine their collection to a select few must include this kind, as none is more robust in growth, and in colour it at present has no counterpart.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**FORCING RHUBARB.**—The earliest stools of Prince Albert introduced into the warm end of the Mushroom house the third week in November are now starting into growth freely, and will be ready for pulling shortly before Christmas. About December 15 a second batch of stools must be put into a similar position. A portion of the permanent bed in the open ground should now be covered either with pots made specially for the purpose, or tubs with the bottoms knocked out. These should then be built round with a sufficient thickness of fermenting material previously prepared by turning, so that the rank steam has escaped. Leaves and stable litter may be used in about equal proportions if there exists any fear that the indoor supply will be exhausted before that covered by leaves alone will be fit for use. Where, however, time is not a desideratum nothing surpasses a bed composed of leaves only, as these retain the heat to the very last, the ammonia arising therefrom imparting flavour to the Rhubarb. The best example of forced Rhubarb I have ever seen consisted of a good-sized bed of the true Prince Albert. Stout stakes were driven in round each stool, so as to form a square; round these hay bands were closely wound, small lights being laid over each, and Oak and Beech leaves well trodden into the intervening spaces. A little straw was then spread over the whole surface, a few extra forkfuls being put on to each light. This plan allowed of the stools being examined from time to time, and when growth was advancing if the weather was mild a little air was admitted by moving the lights on one side. A second bed grew by the side, so that they could be forced and rested alternately. A good deal of harm is annually done to Rhubarb by piling up huge mounds of hot stable manure, which literally stew the crowns before the evil of overheating is discovered. Where it is intended to make a new bed in spring, good-sized healthy pieces with a couple of crowns or leads may be broken off the stools as lifted and laid in in some sheltered convenient corner ready for planting in February or March. The sooner the ground is prepared for the roots the better, as such a rich larder is needed, that time is required to allow the manure mixed in trenching to decompose and the ground to settle. When the plants are put into newly-dug ground in spring it often happens that the roots get an insufficiency of moisture, particularly should the rainfall be under the average; consequently an indifferent growth follows. For the sake of quality as well as quantity, a change of ground is needed every half dozen years. If sensational sticks are required for exhibition, a good thick layer of rich manure may be placed under the stools and the good soil used for filling in. Liquid manure also soon increases the thickness of the sticks.

**POTTING CAULIFLOWER PLANTS.**—This ought really to have been done in October, but the

plants from late sowings—and which are still small—may yet be potted. Some gardeners imagine there is a deal of trouble connected with this process, but this is more imaginary than real, as if much wet and severe frost are kept from them they do not require coddling; in fact, nothing reverts it sooner than Cauliflowers. For potting, use a good holding loam and a sixth part well rotted manure, using pots 2½ inches or 3 inches in diameter, and plunging in a bed of ashes in a well-glazed frame. Plunging I consider very necessary, as when the pots are left above ground the balls are frozen as hard as stones and the roots suffer, causing wholesale bolting as soon as growth commences in spring, or even before. Expose the plants fully on all fine days, and when mild let abundance of air be admitted by tilting the lights well up at the back.

**MUSHROOMS.**—Some beds made up at the beginning of October will now be in bearing, and must be treated to an even temperature, not exceeding 50°. Fire-heat may be employed so as to maintain a heat of 55° if the first beds are later than usual, but as soon as the young white Mushrooms are seen peeping through the surface the first figures must be aimed at. High temperatures—especially where kept up by pipe-heat alone—have a tendency to unduly dry the atmosphere, necessitating surface moistening and frequent floor-sprinkling, which cause the disorder known as blackheads, the crop shrivelling up instead of swelling off. The old plan of covering beds is a good one, saving labour in the end and keeping the surface in a moist state without sprinklings.

**CLEANING SEEDS.**—In some large gardens seed of certain choice strains of vegetables is annually saved, advantage being taken of wet days to dress and clean the same. After cleaning, store in muslin bags and hang them in a perfectly dry, cool place. A cupboard backing up to a wall, the opposite side of which is a fireplace, is about the best place for storing seed. Pea and Broad Bean seed should likewise be looked over in bad weather, and all grub-eaten and faulty seeds removed.

**CARDOONS.**—Where the latest lots of Cardoons are still in the ground, they should now be lifted and placed in a cool dry shed or root store. Get as much soil as possible to the ball when digging them up. Where room is scarce I have known gardeners keep them for a considerable time by suspending them from the roof. If the winter is mild they may, provided they are well covered with bracken, be left in the ground in warm soils, but in damp, low-lying situations they will not stand it, and at any time much wet is liable to ruin the centres. Those already in store must be looked over occasionally, and any that show signs of decay used at once. The root-room generally must likewise be attended to at regular intervals for the same purpose.

**SWEDE TURNIPS.**—Many do not seem to know the value of these roots for a change in the dining room. Here they are sent in twice weekly; indeed some prefer them to the white ones. It must be remembered, however, that roots only from a good rich soil must be selected, and those not too large, or the flavour will be hot and strong. It is fortunate where Swedes are liked, as their use prolongs the supply of other vegetables. Early lots of Coleworts in southern counties which are commencing to split may be kept for some time by lifting with a little soil attached and laying them in a cool, open shed in semi-dry-soil. When rain gets into the split heads, decay soon follows.

**ROUTINE WORK.**—In fine dry weather, opportunity should be taken to clear off any exhausted crops and to get manure wheeled on to all vacant plots at the first approach of frost. In cases where the ground will not be dug or trenched for the present, it is a good plan to tip the manure in one or two large heaps and to throw a little soil over it. This prevents its properties from escaping, and where near the mansion is not so unsightly. Gas-lime may now be safely dug in, not only into plots which are to be sown with Spinach, but also into those to be planted with Cauliflowers, Cabbage,

Beans; indeed the whole garden is benefited by an occasional dose to rid it of all kinds of grubs and purify it generally. On all plots where sowing or planting will not take place until April or May, the best way is to fork it up roughly and then to sprinkle the gas-lime somewhat thickly over the surface. In this way the rain gradually washes it down, and the upper portion gets a larger share of it than when it is dug in at once. After a few dry windy days, get the walks of the kitchen garden swept and rolled again. This will solidify them for the winter, and no more rolling will be needed till spring. In unfavourable weather also shorten stakes which have decayed at the bottom, these being just what one wants for the dwarf Peas on early and second early borders. Pegs and labels either for numbering or writing upon may also be made.

J. CRAWFORD.

### FRUIT HOUSES.

**FORCING STRAWBERRIES.**—The season is now at hand when pot Strawberries are forced for very early supplies. To get good fruit at the end of February or early in March, more than ordinary care is required. In no case do I advocate very early forcing for the mere sake of having fruit at the time named unless there is a special demand for it. Some new varieties are said to force freely at this season, and doubtless many will be started at this date, but as far as my experience goes, no variety can be relied upon unless specially grown, well ripened and given a certain amount of rest previous to forcing. Unless these conditions are fulfilled it would be well to defer forcing for at least a month and give the plants a longer rest. I think much also depends upon the way the plants are rested. I still rely upon the well-known Vicomtesse Héricart de Thury for what may be termed first crop. I am aware all will not agree with my selection, but to a certain extent I am handicapped, and the variety named is of sturdy constitution and forces freely under adverse circumstances. It is of such good quality, too, when grown in strong heat that I advise it for extra early supplies. I admit its size is a drawback and overcropping must be avoided. No other variety can be given so much warmth as this, an important point, as many shifts have to be made in early forcing, few being able to devote special houses to these fruits. I have grown this variety in Cucumber and Pine houses and never had a failure. For succession, Royal Sovereign promises well; it was very good last year. We are not short of really first-class forcing kinds for April supplies, as La Grosse Sucrée is a splendid forcer, having very few small fruits, and if a quantity is desired for a certain date it may always be relied on. I grow this with the newer Royal Sovereign for April supplies.

**TEMPERATURE AND MOISTURE.**—The first is important, as excess at the start ends in failure. To get a free growth at this season a little bottom-heat is of great assistance. This may be given by preparing a good bed of fresh leaves for the plants. The heat must not be above 75° or 80° at most, with 20° lower for top heat. If these conditions are reversed the top growth will start in advance of the roots, and the result will be plenty of leaf growth and few flowers. It may be thought the temperatures advised are fully high, but more warmth is necessary to start the plants now than a month later with a longer rest. In no case do I advise exceeding 55° at night; 5° lower would be better with a free rise by sun-heat during the day. All cannot give bottom-heat as advised, having to force on shelves, where more moisture is required at the roots, also overhead, as the plants dry much sooner. The moisture from the warm bed keeps the plunged plants moister. In fine weather damping overhead will be beneficial and keep the plants free of green-fly. Should this pest attack the plants, fumigate at once and syringe afterwards. Many fail to get very early plants to throw the flower-spikes well out of the leaves. This is owing to want of light or too little moisture. The glass should be kept clean

and the plants as near to it as possible. I do not advise much manure till the flower-spikes are showing, when the plants may be assisted with clear soot water, and when the fruit has set with stronger liquid food. Now is an excellent time to place second batches in Peach houses or vineries just started. The plants move along slowly and make a strong growth, given cool treatment. Many growers top-dress at this season when starting. I do not advise it with plants in good condition. I prefer to rely upon liquid food later on, and a little bone-meal spread on the surface is soon absorbed by the surface roots. The soil if at all loose in the pots should be well rammed, the pots washed, old leaves that have lost colour removed, and the drainage examined before placing indoors. In the case of any varieties which mildew badly, it is well to give a dressing of sulphur, well covering the under sides of the leaves.

**STRAWBERRIES AT REST.**—In a former note I referred to the importance of resting, at the same time pointing out that plants in pots suffer much sooner than those in the open ground. The season has now arrived for all pot plants to receive protection. The best protection is probably cold frames, plunging the pots in ashes or fibre, and removing the sashes in mild weather. If put into fruit houses, care must be taken not to excite the plants. They should be kept cool. I would rather plunge in beds on a well-drained quarter in ashes. Many growers can place on floors of fruit houses that are at rest if due attention is paid to moisture. Many plants have been lost by being severely frozen, losing all the best roots round the sides of the pots when placed in heat.

**FIGS IN POTS.**—Now is a good time to start pot trees to obtain fruit in April. The grower of early Figs will have given the plants special culture with a view to early fruiting. Such plants will now be showing the small embryo fruits on the points of the shoots. Much better results are secured when bottom heat can be given, but it must not exceed 80° at the start. I prefer fresh leaves, or leaves and litter prepared by frequent turning over if the roots are not assisted by hot-water pipes. With healthy plants, the roots when plunged in warm leaves soon push out and lay hold of the plunging material. This saves much watering. Large trees in pits or pots that have been forced yearly soon start if they have been given a good rest, and little heat will be required. A low night temperature is advisable at the start—50 to 55°, according to the weather, with a rise of 10° by day—frequently syringing the trees overhead on fine days and damping all parts of the house several times daily. As the leaves develop the heat may be increased, but only slightly, as if the fruit is too far ahead of root growth it turns yellow and drops. Less syringing will be required as the trees get more leaves, and the roots may then be assisted with liquid manure. In dull, sunless weather it is better to rely upon moisture from the house than overhead syringing, which causes rust on the leaves and fruit. Dryness at the roots must be guarded against; on the other hand, stagnant moisture is equally injurious, so that perfect drainage is important. As soon as it can be seen which fruit takes the lead it is well to thin. The shoots should be pinched at the fifth or sixth joint or leaf from the fruit, and any fine spray or sucker growth cut away. By building up well-balanced trees a second crop is assured and good wood for next season's forcing.

**MELONS.**—The season for ripe fruit is now nearly over and a few words will suffice as to bearing plants. The early part of the autumn was more favourable for late plants than is often known, so that fruits have been more plentiful and of better quality. Those who have late fruit just pushing will need to give a night temperature of 65 to 70°, with 10° higher by day, with as much warmth as possible by sun heat. Very little moisture at the roots is necessary unless the plants are in shallow beds heated by hot water. The foliage must be kept healthy to the last, and as the fruits colour, flavour may be assisted by

cutting and placing on a warm, dry shelf. Those who value early fruit would do well to prepare plants for the first crop. By sowing now good plants may be had to plant early in February. A warm bed near the glass is necessary, sowing the seed in 3-inch pots in good compost made firm. For very early supplies I prefer a small or medium-sized kind with a thin skin. Such kinds do well in large pots if a Melon house is not available. G. WYTHES.

## CHRYSANTHEMUMS.

### NEW AMERICAN CHRYSANTHEMUMS FOR 1895.

THOSE who are at all familiar with the position of horticulture in the United States of America need no reminding of the continued popularity of the Chrysanthemum in that country. Last season, besides the private displays and trade exhibits, there were Chrysanthemum shows held from one end of the Union to the other by the florists' clubs and horticultural societies to an extent which, if equalled, has probably never been surpassed. Places so far apart as Boston and San Francisco, Chicago and Baltimore, have now commenced a regular series of annual exhibitions of the Chrysanthemum, with the result that many intermediate cities are following their example, and consequently spreading a love for the popular favourite in quarters where it was only imperfectly known before.

The vast area over which the Chrysanthemum now reigns in the States is one of the chief difficulties with which the American Chrysanthemum Society has to contend, and one which most of us in England are not likely to appreciate to the full. As at present constituted, that society does not undertake the organisation of shows on its own account, but deals with other matters pertaining to the flower, such as the registration of new seedlings, a work that might usefully be imitated here in Europe, the determination of synonyms, and more recently the appointment of local committees to examine, in much the same way as our floral committees do, new varieties that appear during the season. It may perhaps be patriotic, but it is scarcely impartial that a rule appears to exist that no foreign seedlings can be the subject of any award by the American society. From the proceedings of the tenth annual convention of the Society of American Florists held at Atlantic City, N.J., in August, 1894, of which the American Chrysanthemum Society is a branch, it seems that the local committees consist of three members each, and that they were appointed to examine new Chrysanthemums in the following cities: Boston, New York, Philadelphia, Cincinnati, and Chicago. It is interesting to quote the conditions upon which the novelties were shown, inasmuch as they differ in some respects from our floral committee regulations. Meetings were appointed for October 20 and November 10, but in the published reports which appeared in the *Florists' Exchange* they appear to have been held on November 10, 17, and 24:—

Not less than six blooms of each variety to be shown, and these to be only such varieties as have been given at least the second year's trial.

No member of a committee shall exhibit his own blooms before a committee of which he is a member.

It will be well for those who exhibit seedlings under number 1 to also provide the committee with a name to be used in case the variety is commended, so that they may be reported upon by name rather than number.

At the same meeting it was resolved, as some doubt appeared to exist as to the proper name, that the society should be known as the Chrysanthemum Society of America. During 1894 new Chrysanthemums were registered from sixteen different raisers, and a further list is given of names registered, but the varieties had not then been distributed.

The proceedings of the local committees having been forwarded to the secretary of the society, the

results are tabulated and summarised, in which form they appear in the *Florists' Exchange*. To anyone interested in the importation of new American varieties the report given by the secretary will be useful, for it states the name of the flower, date when shown, where shown, the exhibitor's name, type and colour, whether worthy of the society's certificate or not, and the remarks concerning it. The principal exhibitors at these meetings appear from the report to have been Mr. T. H. Spaulding, Messrs. Nathan Smith and Son, Messrs. E. G. Hill and Son, and several others, but those named are especially known in this country as having contributed to enlarge our lists by obtaining some very meritorious novelties. There will be no need to refer to them in this article, as a perusal of former contributions on the subject will supply any details that may be necessary.

In the list appended to this paper will be found some names to which no raiser is appended. These, it should be mentioned, are varieties of Japanese or Californian origin gathered from sources where such material is not supplied. One grower whose name is well known has this year for the first time dropped the practice of giving raisers' names in his list, which it is to be hoped he will resume again next year, because there is often great difficulty in tracing the origin of some of our best American Chrysanthemums.

The incurred Japanese section seems likely to receive large additions from the American novelties of 1895. This is a class that some eminent specialists seem to have no great liking for, but it has been a steadily increasing one, and the majority of the varieties, if we except those of M. Ernest Calvat, have been received from America or from Japan *via* America. The term "early" which will be found in some of the descriptions means that the flowers are October blooming kinds in the States. Here in England, however, our method of cultivation may cause some variation in the season of their flowering. As regards habit, it is some satisfaction to find that many of these new-comers are dwarf, and indeed it would appear that the era of the 9-foot and 10-foot varieties like Mme. Audiguier and Mme. Bertier Rendatler has been brought to a close. Three feet and 4 feet in height is what is claimed to be the limit in many of the undermentioned sorts.

*Amber Ada Spaulding.*—An amber sport from Ada Spaulding, similar in all respects save colour.

*Amoor.*—Very broad petals, colour rich reddish brown, reverse silver-bronze.

*Arctic.*—Colour pure glistening white, faintly shaded salmon.

*Autumn Leaves (Spaulding).*—Japanese; flat petals, colour creamy white, mottled and striped red, tipped cream or light yellow.

*Bangkok.*—Incurred; colour bright yellow.

*Brightend (Spaulding).*—Japanese; slightly reflexed, deep crimson, very dwarf.

*Bronze Giant (Spaulding).*—Japanese incurred; colour golden yellow, heavily shaded deep crimson.

*Bright Eddy (Vaughan).*—Colour silvery rose and purple.

*Camille d'Arrille (Spaulding).*—Japanese; white, tinted salmon when opening.

*Capt. J. C. Ainsworth.*—Colour pure glistening white, large blooms.

*Castle Peak.*—Spherical bloom, fine straight petals, colour white, suffused pink.

*Chipeta (Smith and Son).*—Incurred Japanese; colour quite similar to ripened Oak leaves, strong grower.

*Cristalina (Vaughan).*—Colour snow-white, early.

*Dean Hole (May).*—Incurred; broad petals, white, shaded pink, changing to pearly white.

*Diavola (Spaulding).*—Japanese; colour a mixture of lemon, white, and red, under petals white, shaded pale lemon, centre ones striped red.

*Dr. W. J. Wokeley (Spaulding).*—Japanese incurred; colour chrome-bronze, under surface of petals shaded red.

*Edith Smith (Spaulding).*—Japanese; flat broad petals, ivory white, globular flower, early.

*E. M. Bigelow (Dorner).*—Incurred; colour deep reddish orange, dwarf.

*Esther Hancock (Spaulding).*—A sport from Ada Spaulding; colour yellow, rather dwarf.

*Emma N. Crosby* (Spaulding).—Bright golden yellow, lower petals reflexing, forming a globular flower, dwarf.

*Experiment* (Spaulding).—Japanese; broad spreading bloom with narrow petals, colour shrimp pink.

*Ezeta* (Smith).—Japanese; an improved Roballion; colour pure bright yellow, early, dwarf.

*Fisher's Torch*.—Large blooms, colour fiery red.

*F. L. Atkins* (Pitcher and Manda).—Japanese reflexed; colour pearly white, long broad petals, globular flower.

*Formosa*.—Bright purple.

*Fred. Watz* (Bock).—Florets partly incurved, colour pale pink, dwarf.

*G. E. Goodman*.—Globular blooms, colour light lemon-yellow.

*Gold Dust* (E. G. Hill).—Incurved; colour golden yellow.

*Golden Castle*.—Colour deep golden yellow.

*Hallow'een* (E. G. Hill).—Incurved; reverse pinkish grey, inside r. se-violet.

*Helen Bloodgood* (Spaulding).—Japanese incurved; clear pink without any shading, a large, globular flower.

*H. W. Rieman* (E. G. Hill).—Japanese; deep golden yellow.

*James Weir, Jr.*—Anemone; broad ray florets, colour dark velvety crimson, centre tipped golden yellow.

*Jayne* (Vaughan).—Incurved blooms; colour dark, shaded rose.

*J. E. Layer* (Pitcher and Manda).—Japanese; colour yellow.

*Jennie Falconer* (Spaulding).—Japanese incurved; self coloured, lemon-yellow, dwarf.

*J. H. Troy* (Pitcher and Manda).—Japanese; colour white, broad petals, globular blooms, early.

*Katherine Leech* (Graham).—Reflexed bloom, colour pure self pink, early.

*Latest Fad* (Spaulding).—Japanese; ribbon petals of great length, colour yellow, mottled and striped with crimson and bronze.

*Lottie Alter* (Spaulding).—Japanese incurved; broad petals, colour ox-blood-red, reverse lighter, dwarf.

*Lurline*.—Japanese; similar to Good Gracious, colour deep silvery pink.

*Marie Vallau* (Spaulding).—Japanese incurved broad petals, colour soft cameo-pink, deeper towards the centre.

*Marion Abbott* (Spaulding).—Japanese incurved; broad petals, for a deeper flower, pink, the colour of Rose La France.

*Maud D. Reynolds* (Spaulding).—Incurved flower, lower petals reflexing; colour deep canary-yellow.

*Millbrook* (Dorner).—Of the Vivand Morel type; colour bronzy salmon-red, dwarf.

*Miss Elma O'Farrell* (Dorner).—Reflexed blooms; colour salmon-rose, dwarf and late.

*Miss Georgiana Pitcher* (Pitcher and Manda).—Incurved blooms; colour yellow, dwarf.

*Miss Georgie Crompton* (Spaulding).—Broad flat petals, globular blooms, self-coloured golden yellow.

*Miss Gladys Spaulding* (Spaulding).—Incurved; globular bloom, colour white.

*Miss Louise D. Black* (E. G. Hill).—Japanese; colour reddish orange.

*Miss M. M. Johnson* (E. G. Hill).—Japanese incurved; colour deep golden yellow, early.

*Mrs. Chas. Woolsey* (Henderson).—Colour pure white, early.

*Mrs. H. Robinson* (Pitcher and Manda).—Incurved; said to be of the Queen of England type; colour white, early.

*Mrs. H. L. Romig* (Graham).—Incurved; colour creamy white, dwarf.

*Mrs. H. W. Emerson* (Dorner).—Colour yellow; considered better than H. L. Sunderbruch or Eugène Daillidouze.

*Mrs. J. H. White* (Spaulding).—Japanese; crimson, resembling Cullingfordi, reverse gold, dwarf.

*Mrs. Moses J. Wentworth* (Vaughan).—Chinese; full and deep, colour rich yellow.

*Mrs. M. R. Parker, Jr.* (Spaulding).—Broad, incurving petals, inside deep pink, reverse light silvery shade, dwarf and robust, early.

*Mrs. S. T. Murdock* (Dorner).—Colour light rose or pink, dwarf.

*Mrs. Thos. G. Weidersheim* (Graham).—Light pink, dwarf and early.

*Mrs. W. A. Bryant* (Pitcher and Manda).—Broad petals, colour chrome-yellow.

*Mrs. W. H. Hurley* (Graham).—Japanese; deep orange-yellow, dwarf and early.

*Mrs. Wm. H. Rand* (Vaughan).—Japanese; fine long, twisted petals, golden yellow.

*Morocco*.—Dark velvety maroon, reverse orange, large blooms.

*Mount Everest*.—Curious twisted petals, pure snow-white.

*Mount Hamilton*.—Reflexed bloom, bright red, shaded crimson.

*Nellie Elverson* (E. G. Hill).—Incurving blooms, petals deep Indian-red, faced with bronze.

*Nellie P. Moulton*.—Japanese incurved; colour bright yellow, without shading.

*Nemesis* (May).—Straight, broad petals, colour similar to Carnation Daybreak, dwarf and early.

*Nyanza* (Smith and Son).—A seedling from G. W. Childs, possessing the same brilliancy of colour, golden reverse, dwarf.

*Oakland* (Dorner).—Full deep blooms, clear shade of terra-cotta, rather dwarf.

*Octoroon* (Spaulding).—Japanese incurved; broad petals, colour ox blood red, reverse lighter, dwarf.

*Olympus* (May).—Round flower; base of petals white, with delicate shade of pink outside.

*Paridis*.—Anemone; colour lemon-yellow.

*Parting Guest* (Spaulding).—Japanese; globular blooms, colour white, lower petals tinted rose-lilac like Puritan, dwarf and late.

*Perfection*.—Foliage variegated and mottled with pale pea-green and white, blooms pencilled light pink.

*Philadelphia* (Graham).—Japanese incurved; very globular bloom, grooved pointed petals, colour white, tinted primrose at tips. Awarded silver-gilt medal, N.C.S.

*Pride of California*.—Colour rich chrome, shading to bright golden centre.

*Princess Bonnie*.—Anemone; clear golden yellow, full centre.

*Port Imperial*.—Deep lavender-pink, reverse silvery.

*Quito*.—Japanese; colour rich red and terra-cotta.

*Radiance* (E. G. Hill).—Incurving blooms, colour similar to Golden Wedding, early.

*Satisfactio*.—Anemone; ray florets chrome, centre deep yellow, intermingled with crimson.

*Sophia Sievers*.—Long broad-pointed petals, colour white.

*Sunrise* (May).—Very broad petals, inside bright terra-cotta, reverse old gold, blooms semi-incurved, dwarf and early.

*Tasmania*.—Dark crimson intermingled with white, and parti-coloured petals.

*Thalia* (Smith and Son).—Similar in form and size to Niveum; colour light lavender-pink, passing to rose, late, dwarf to medium.

*The Egyptian* (E. G. Hill).—Japanese incurved; similar in form to C. B. Whitnall, dark velvety red.

*Triby* (May).—Petals slightly twisted, colour clear white, a bold round flower.

*W. B. Dinsmore* (Pitcher and Manda).—Japanese incurved; golden yellow, petals of great substance.

*White Lotus*.—Incurved; colour cream-white.

*Yukon*.—Incurved; colour pure white.

*Zipangi* (Smith and Son).—Outer petals reflexed, centre ones incurving, colour crimson-lake inside, reverse buff.

*Zulinda* (May).—Incurved; inside of petals clear rose pink, reverse silvery pink.

C. HARMAN-PAYNE.

P.S.—During the time the above article has been in the printer's hands I have learned that the American Chrysanthemum Society has resolved to allow foreign seedlings to be shown on similar terms to native productions, excepting the rule as to a second year's trial. This appears to be an act of fair-mindedness which European raisers will not fail to appreciate.

#### COARSE CHRYSANTHEMUM BLOOMS.

It is somewhat strange that the taste for huge, coarse-looking Chrysanthemums is so long-lived, and that scarcely a stand of blooms is exhibited that does not contain one or two of these gigantic specimens, that more often than not mar the whole. I was pleased, however, to note that the variety Etoile de Lyon was less numerous than usual throughout the late shows, and it would be no great loss were that ugly flower entirely discarded from exhibition stands. As a very late sort it has its uses and is occasionally presented in fair form, but not often enough to redeem its character. It is, to my thinking, one of the least beautiful of all Chrysanthemums. International was frequently met with. Now this sort has but one recommendation, and that is, it covers a very large space on the show stand. There is in it a notable absence of anything striking either in colour or form. Mrs. C. Harman-Payne was

much in evidence everywhere, and was huge in size, but bore a faded look. One magnificent bloom was seen at the Aquarium show in November, quite exceptional in form and colour. A single specimen of presentable aspect, however, in an exhibition so extensive as the above named is scarcely enough to commend it. But of coarse flowers, I think Van den Heede the ugliest. Half a dozen blooms of this variety were noted in a class for six of any kind, and the judges rightly passed them in favour of smaller, but more beautiful sorts. It is a huge flower, the petals stiff and ungraceful, and the colour a dull buff shade. Probably late buds might aid the growth of better flowers in the case of this sort. Still it is one, were it not for its size, which would soon be discarded. Duke of York is another giant only on very few occasions seen in a taking form. The general character shows the dull lilac tint of the outside of its florets. It is exceptionally large, and this seems to be the only cause for its popularity. Mrs. E. W. Clarke has not been seen often this autumn, nor is the loss great, for as a coarse, colourless bloom it has few equals. Cendor was noted in a few stands, especially at country shows. This is a huge flower, quite outclassed now-a-days. I cannot remember having seen a single bloom of a rather popular kind of a year or two back, namely, Mrs. T. Denne. This dull rose-coloured Chrysanthemum will not be missed. It does not add to the beauty of a stand of flowers at a show, nor to a home display. Miss Ethel Addison, to my taste, belongs to the coarse, ungainly section, a remark that applies also to the newer sort from Australia, Pride of Madford, and Vice-President Calvat. H. S.

#### COLOUR IN CHRYSANTHEMUM BLOOMS.

DIFFERENT localities have undoubtedly a great effect upon the colours of these flowers, as have also manures. I noticed that the blooms exhibited at the Aquarium by a cultivator from a southern seaside town were exceptionally bright. I am inclined to think, indeed, that the flowers of Vivand Morel, Charles Davis, and Miss Dorothea Shea put up by Mr. Streadwick, an amateur from St. Leonards-on-Sea, were never matched for depth and richness of colouring. But the greatest differences are caused by the time (whether early or late) we select the flower buds. It is no uncommon thing for persons to send me blooms of varying shades of colour from well-known sorts, fancying they have obtained valuable sports. A few years back the white Etoile de Lyon was in demand, and many a specimen was seen almost white in colour, this variation being due entirely to the taking of early flower buds. The most common occurrences, however, are connected with the variety Vivand Morel and its sport, Charles Davis. The latter from early buds will come quite yellow, and in slightly darker shades reach the most esteemed shade—a bronzy-rose, according to the time the buds are secured, the terminal or last buds, when the plant is naturally grown, being those that produce this taking shade. In the same way the type is quite white when early flowers are grown. These vary to a lovely mauve-pink from late buds. The florets, again, are of better substance from late buds in both cases. Graphic, a new variety, is very changeable in colouring. Very fine deep flowers of it were exhibited the other week quite white, and a fortnight later I saw the same kind of a lively pink colour, the form of the blossoms differing too in a remarkable manner. Mrs. W. H. Lees is another sort of variable form. Early in the season its florets are of extra length. These droop and hang loosely, with just a curl at the tips. On buds obtained at a medium period the florets, instead of drooping, curl upwards and build up a bloom quite pyramidal in formation. A flower of this shape was seen at the last floral committee meeting of the National Chrysanthemum Society, and, like those blooms from early buds, was almost white in colour. Now from terminal buds I have the sort pink with shades of white, but the form drooping. We have thus three distinct forms in one variety.

The terra-cotta-coloured Miss Dorothea Shea is hardly recognised when early buds are taken. It then assumes a dull colour, whilst the shape of bloom is anything but striking. Another instance is the sort Wm. Seward. From early-formed buds the florets are short, stiff and dull-coloured, but when late buds are depended on the blossoms are vivid crimson, the florets long and hanging down in a graceful manner. President Borel is an uninteresting variety when early buds are selected, the late blooms being especially rich in rose-crimson colouring. In fact, all highly-coloured sorts are best obtained from late buds. E. Molyneux is seldom seen in good form because of early blooms being grown. These, almost before they are open, fade off to a dingy brown colour. At its best there is no Chrysanthemum more striking for its colour. Col. W. B. Smith is sometimes seen reflexing its florets. In this state the colour is certainly rich, but not nearly so taking either in colour or form as when it is selected from late buds. One might go on with names. My idea in this note, however, is to point out the fact that in selecting early buds with the desire to obtain gigantic flowers, we often so alter the character of varieties as to quite lose their beauty, and excellent sorts may be condemned before they have been properly grown.

H. S.

#### American show Chrysanthemums.

There is always a keen interest on both sides of the Atlantic to know the relative positions of the popular varieties. Many of the finest English kinds do not seem to do well in America, and some of the American seedlings when imported here do not maintain their reputation on our show boards. Philadelphia, to wit, has not been shown in a single winning stand in the leading classes at our shows this year. The varieties of American origin that have done best with us up to the time of writing this note are the following: International, H. L. Sunderbruch, Hairy Wonder, Col. W. B. Smith, W. H. Lincoln, Eda Prass, Lord Brooke, W. W. Coles, Niveum, Mrs. Dr. Ward, W. Tricker, Puritan, G. W. Childs, W. G. Newitt, Primrose League, Good Gracious, Violet Rose, Lilian B. Bird, The Queen, Golden Gate, Waban, Mrs. W. H. Lees, Mutual Friend, Beauty of Castlewood, Mrs. E. W. Clark, Miss Ethel Addison, Mrs. E. G. Hill, Miss Anna Hartshorn, Duchess of Wellington, Mrs. C. W. Wheeler, and A. H. Fewkes. Of these, International is coarse and inconstant in colour; Col. W. B. Smith has been exceptionally fine and deep in colour; W. H. Lincoln, deep and pure in colour; G. W. Childs, very rich and probably finer in its intensity of crimson than ever; Golden Gate, large, and of a beautiful rich shade of yellow.—CHRYSANTH.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Golden Gate.**—This rather late-flowering sort is notable for a striking shade of colour, a tawny yellow, quite distinct from any other.

It belongs to the Japanese class, the petals being reflexed. The growth is excellent. The variety was introduced a few years back from Japan.—H.

**Chrysanthemum M. Chenon de Leche.**—This variety is among the best of E. Calvat's seedlings, being so distinct in shade of colour. The combination is yellow and rose, which is generally described as crushed strawberry. Its flowers are full and deep and the growth all that one can desire.—H.

**Chrysanthemum Reine d'Angleterre.**—When first seen last year I thought this too coarse, but this season the fault is not noticeable. I think it will replace Etoile de Lyon, so popular with exhibitors. It is a very large flower, with long, flat, slightly drooping petals. The colour is a pleasing shade of rosy white, the growth remarkably dwarf and sturdy. The variety will be much esteemed for exhibition.—H.

**Chrysanthemum Edith Tabor.**—One of the best of this year's novelties is the above. It would seem difficult to improve in yellow Japanese Chrysanthemums, yet this stands out as a decided gain. The

Puritan and Mrs. Alpheus Hardy. It certainly does not partake of the latter weakly grower in habit, being of extra strong growth. The blooms are composed of numberless long, wide and thick florets, which droop and slightly curl at the tips. The colour is white, faintly tinged pink towards the centre of the flower.

## ORCHIDS.

### SEASONABLE NOTES ON ORCHIDS.

THE dullest months of the year are now past as regards Orchid flowers and the houses have quite a gay appearance, owing to the number of species in flower. Perhaps the brightest bit of colour of all now is the pretty *Sophronis grandiflora*, the plants having made a capital growth and flowered more freely than usual. There is a great difference in the tints of colour

*Gymnogramma triangularis.* From a photograph by Miss Willmott, Warley Place, Essex. (See p. 437.)

colour is rich; the florets, extra long and fairly wide, hang down gracefully, and have just a slight curl at the tips. It was raised from seed in this country, and will be sought after on account of its charming character.—H.

**Chrysanthemum Australian Gold.** This is one of M. E. Calvat's latest novelties; in fact, the only one he has presented in good form so far this year. We must not talk yet of this raiser's strain being run out. It is only that he has failed to grow the blooms as well as usual. The above-named is a massive and beautiful bright yellow Japanese flower of a drooping character, and the reverse of the florets shows a lemon tint, a pleasing combination.—H.

—M. Ernest Calvat desires us to state that his new seedling, certificated by the N.C.S. on October 30 under the name of Australian Gold, should properly have borne the name "Calvat's Australian Gold," under which name it will be catalogued and sent out by him.

**Chrysanthemum Mrs. H. Weeks.**—This very handsome and massive Japanese variety is an English-raised flower and said to be a cross between

where many plants are grown, and although all are very effective, none can compare with the bright scarlet type, usually characterised by its longer thinner pseudo-bulbs. I say usually advisedly, as I have been deceived on at least one occasion by the appearance of the plant, and only found out my mistake when it flowered. Well-established plants, it may be noted, bloom much more profusely than newly-imported or semi-established ones, so that growers who may be flowering the latter for the first time must not be surprised if the amount of bloom does not quite come up to their expectations. Such should endeavour to strengthen their plants as much as possible by removing the blossoms before any sign of distress is apparent, treating them well during the ensuing season. There is no need to enumerate the many fine Orchids now in flower, as notes on several of these have recently appeared in THE GARDEN, as

well as a capital and very useful list on p. 391, November 22. But there is one point in the arrangement of the flowering house that it may be out of place to notice, and that is the varied effects that may be produced, even with the same plants, by moving and re-arranging in an altered style. It is too often the case that plants are taken to the house in question and arranged—it may be very naturally and tastefully—but there they remain in the same, or nearly the same, position until the blooms fade, visitors seeing them day after day until they are tired. Now, it is a very simple matter to avoid this sameness by the plan mentioned above. For instance, supposing a group of plants arranged in the usual way with *Cattleyas*, *Odontoglossos*, *Cypripediums* and others in mixture, with spikes of *Calanthe Veitchii* or some similar kind rising in prominent positions to break the lines and prevent any possibility of flatness, careful and thin arrangement and a judicious blending of the colours render such groups very attractive. A change may be made from this by breaking up the group, so to speak, into three or four mounds, each being composed of one or the other species and suitable greenery, massing the plants so as to make a fine display of colour, and arranging any that by reason of their miscellaneous character cannot be grouped between the mounds referred to. A still further variation will be made by altering the position and shape of the mounds, or by keeping one kind as a groundwork and dotting other kinds irregularly amongst them or in any other way that occurs to those in charge of the work. This makes the most of the material at command, and also keeps up the interest of visitors. More fire-heat has now to be applied in the flowering house, and as much damping is inadmissible, insects sometimes make headway upon the plants while there. It is a good plan to look them over carefully after flowering and before returning them to their various houses.

The work is now chiefly of a routine character, and consists in keeping the temperatures regular, damping judiciously, but not too abundantly, and giving as much air as possible without unduly lowering the temperature. With regard to watering at the roots, everything depends upon the species and the state of growth. *Cattleyas* of all kinds will need greatly diminished supplies, small plants of course requiring more attention than those of a larger size and having a greater body of compost about them. Where such as *C. Aclandiae*, *C. Walkeriana* and others are grown on blocks only lightly dressed, watch carefully for or rather anticipate the first signs of distress, as it is not easy to bring these into a healthy condition when once they are badly shrivelled under cultivation. The kinds that require most water are those which grow late in the season, including *C. Mossiae*, several plants of which are still unfinished, and many of the intermedia and guttata types even now rooting freely. Besides these there are several that, owing to the great heat during September and early October, started to grow out of season. *Laelia purpurata* too is in full growth, and should have the lightest and warmest position with plenty of water when the weather is bright. The Mexican kinds are nearly all at rest, and are kept well on the dry side and cool, especially *L. majalis*, the most beautiful of this section. The later *Dendrobiums* are now about finished, such kinds as *D. macrophyllum* and *D. Dalhousianum* now showing the terminal leaves. The buds are well advanced on *D. Wardianum*, *D. nobile*, and *D. aureum*, and successional plants of all these may now be placed in heat. There is no need to water them much at

the root, as the old pseudo-bulbs contain plenty of nourishment as yet. Woodlice and small snails are apt to be troublesome at this season by eating the soft and tender flower buds as they appear at the nodes. These must be trapped by placing pieces of potato about the plants and examining them daily, also searching at night with a lantern, or the loss of some flowers is almost certain. The deciduous kinds now in the cool house having lost all their foliage may be kept quite dry, that is if they have been properly ripened, as no shrivelling of the pseudo-bulbs will take place. Over-watering in winter is frequently the cause of failure with *D. Bensoniae*, *D. Parishii*, and several others, as may be seen in the spring by the loss of roots. With the evergreen kinds such as *D. densiflorum* and allied species it is different. These must not be quite dried off, but at the same time they do not require more than is absolutely necessary to keep the pseudo-bulbs plump. They are safest in a house that does not fall much below 55° at night, except when very cold outside. The earlier *Pleiones* as they go out of flower must be repotted, but as they have been very recently noted it is not necessary to go into details upon this point. Suffice it to say that the sooner they are potted after flowering the better, and that the greatest care is needed in watering afterwards. The cool house is now beginning to get more interesting, especially where plants are flowering for the first time. Here also a watchful eye must be kept on the spikes, as they are an irresistible attraction to slugs. Any of the well-known methods may be resorted to, but be sure and be before them, or the result of one night's depredations may mean the loss of many spikes, and thus a season's growth and trouble will be thrown away. If not already done, *Disa grandiflora* should be repotted without further delay, as the new roots are, or soon will be, starting, and it is well to anticipate these. Considerable care must be taken with this Orchid both in cleaning and draining the pots and the preparation of the compost, as upon these and other seemingly unimportant details much depends. Requiring so much water at the roots while growing, the medium for these must be lasting. The roughest and best of peat fibre must be mixed in equal proportions with fresh growing Sphagnum, and plenty of good rough lumps of charcoal and crocks should be added as it is placed in the pots. The leaves should be damped over lightly with the syringe several times daily, and when the roots are running freely, plenty of water must be given.

All the temperatures as given last month will be suitable, but the night temperature may drop a little on very cold nights rather than press the fire-heat too strongly. R.

**Odontoglossum Cervantesi.**—The varieties of this pretty *Odontoglossum* are again flowering, the large and beautiful *O. C. decorum* being prominent amongst them for its great size and substance. The flower of the typical form is about 2 inches across, the sepals and petals rosy white with basal stripes and dots of reddish brown; the lip yellow at the base and also marked like the sepals. It is a native of Mexico, and thrives well in a cool, moist house close to the glass. It may be placed in small shallow pans just large enough to allow of about an inch of peat and Moss being placed around the plants, and requires abundance of water at the roots all the year round.

**Cattleya superba splendens.**—I have sent you a spike of *Cattleya superba splendens*. The flowers, five in number, are very sweetly scented and of good colour. The plant has been in the Sharcombe collection of Orchids for several years,

but this is the first time it has bloomed. It has been grown in a hanging basket in the stove and seems to do well with the treatment.—C. Mounsdon, *Sharcombe Gardens, Wells*.

\* \* A remarkably handsome Orchid. In the variety sent the flowers are larger and the sepals and petals longer than in the type. The sepals and petals are deep purplish rose, the lip white at the base, rich crimson in front, with several lines of golden yellow running along the middle. It forms a fine companion to the typical plant when the two are grown together.—Eiv.

**Cattleya aurea.**—I have sent you per to-day's post a bloom of *Cattleya aurea* for your opinion. It seems to come near to *C. aurea* (Young's var.). The bloom is one of two on the spike from an imported plant just established, and will probably improve.—HUGH J. HUNTER, *Edinburgh*.

\* \* The flower of *Cattleya aurea* sent is a magnificent variety, large and brilliantly marked. It is not the variety you name, but it is equally beautiful. The yellow side blotches on the lip are exceptionally rich and deep, and the marginal band of rosy purple stripes gives the flower a very distinct appearance. Being rather late in the season for this variety, I have no flowers with which to compare it, but do not hesitate to pronounce it one of the very best varieties in existence, especially if, as you suggest, it improves under cultivation.—H. R.

**Extraordinary plant of Dove Orchid.**—During the summer mention was made in the columns of THE GARDEN of a plant of *Peristeria elata* having a flowering stem furnished with twenty blooms, this being thought by the writer to be an exceptional occurrence. At that very time might be seen in a small plant stove at The Grange, Winthorpe, near Newark, the residence of Mr. J. S. Branton, a plant of the same Orchid carrying two stems, one about 5½ feet and the other a foot or so less in height, and having on them forty and thirty flowers respectively. The stems were as large as ordinary walking sticks, the leaves of immense size and of a fine green colour, while it is almost needless to say the individual flowers were correspondingly fine. The plant, growing in a pot some 12 inches in diameter is, I believe, potted principally in loam and open material. It is fortunate that Mr. Dench, the gardener, has two other young plants coming on which look remarkably healthy, as the great strain put upon the energies of the parent plant in perfecting two such abnormal flower-stems has had the effect of lessening the size of the present year's bulbs.—J. C.

**Dendrobium aureum.**—This species is to some extent looked down on by Orchid growers, owing probably to its small size, but its many good points ought to secure for it a place in the most limited collection. It takes up very little space, produces a very good flowering return, and is besides cheap and easily grown. The flowers are produced from the nodes after the leaves have fallen in short side racemes of about two or three. These last long in beauty and are sweetly scented, the fragrance resembling that of Violets. *D. aureum* may be grown in pots or buckets in a mixture of peat and Sphagnum, with plenty of small crocks and charcoal added. If placed in pots the base of the leading pseudo-bulb may be kept slightly above the rim, and the compost must be arranged in a cone-shaped mound, from this bedding it firmly and neatly trimming off all ragged ends of peat. The best time to repot is early spring when the new growths are appearing, and the plants must be placed in a light, sunny position in the East India house. The roots are vigorous when once they obtain a hold of the compost, and when growing freely require plenty of water. The pseudo-bulbs are usually complete soon after midsummer, and they must then be placed out of doors in full sun for a few weeks to thoroughly harden them, well-ripened bulbs being the sure forerunners of a bountiful crop of flowers. After the foliage has fallen very little water will be needed, and the plants are well suited if given a place in a vinery from which which early fruit has been taken or in any sunny greenhouse until the

nodes begin to burst, when they may be returned to the warm house and will rapidly form flower-buds. The blossoms are light primrose with velvety crimson markings on the lip. It is a widely distributed plant naturally, being found in various parts of India and Ceylon, and was introduced into this country in 1837.

**Angræcum Scottianum.**—The small-flowered section of this genus is a very pretty and interesting set of plants, and the above is no exception to this. The leaves are small, little more than 3 inches in length, the flowers pure white, about 2 inches across, usually produced during the autumn and early winter months. This plant does well in small teak-wood baskets, with a few large pieces of charcoal and a little Sphagnum Moss about the roots. The greatest care is needed in fixing the plants. If this is done and they begin to root freely, they are sure to do well if properly treated in other ways, but if rocking about with the least vibration, the roots cannot get hold of the baskets or their contents, and consequently the plants become sickly and lose their leaves. Though not so fond of sunlight as many Orchids, too much shade is not advisable, as this tends to a soft and ill-conditioned growth, that rarely produces anything like a flowering return. The bappy medium, then, is what must be aimed at not only in this, but also in watering. The appearance of the species shows that it does not require drying off while at rest, but too much water during this period must be guarded against. A safe plan is to let the Moss be quite dry before giving a fresh supply during winter, in summer keeping it always green. It is a native of the Comoro Islands, and must be grown in the warmest house.

## STOVE AND GREENHOUSE.

### CARNATIONS IN POTS.

THE self or border Carnations that naturally flower during the summer months are just as well adapted for pot culture as are the tree or winter-flowering and Malmaison types. The illustration here given shows a finely grown and well-flowered plant of the popular Carnation Mrs. Reynolds-Hole carrying twenty good flowers in various stages of expansion besides numerous buds, and is a very different kind of pot plant from those some of us are familiar with by seeing them so often at the annual Carnation show. The Carnation Society, however, moving with the spirit of the times, now provides a class for pot plants not so closely disbudded and stiffly tied, whilst much might be said in favour of growing Carnations more extensively in this way. It gives an alternative course to those who, from peculiarities of soil or situation, are not successful with this flower in the open ground. Pot plants are under the most perfect control of the grower, and his success is in proportion to the cultural skill brought to bear upon them. They may be specially commended to the attention of those who have unheated frames or houses, as pot culture of open-air kinds does not imply or suggest forcing, a system of treatment that these Carnations resent. The variety here shown, however, and any other standard kind grown in this way may be brought into bloom a little in advance of the plants' natural flowering season outside if that is desired by keeping them under glass throughout, always allowing an abundance of air, or the flowering may be retarded to the usual period by keeping the plants in the open air from the warm spring days onwards.

**Tulip Chrysolora.**—I consider this by far the most useful early forcing yellow Tulip. Canary Bird bears the reputation of being slightly ear-

lier, but the difference is so very trifling as not to be worth notice. Canary Bird has one fault, that of being rather weak in the stem, and as it usually grows to a good length the flowers are liable to droop when cut and placed in water, instead of keeping erect and showing their full beauty. Chrysolora, on the other hand, has a stouter habit and holds itself erect, the individual flowers also being much larger than those of Canary Bird, although perhaps not quite so brilliant. I use this Tulip largely in January for table decoration, the rich golden colour being very effective by artificial light. It is not quite so expensive to buy as Canary Bird.—J. C.

**Notes on forcing shrubs.**—In many gardens preparations will now have to be made for forcing various hardy flowering shrubs. No place answers better than an old-fashioned vinery having a pit in the body of the house, as this can readily be filled with Oak or Beech leaves, and thus a genial top and bottom-heat afforded. Of course, any

are grown in the home nursery for two years are employed. Care must be taken not to plunge fully any plant brought into the house as soon as the pit is filled with new leaves, or excessive heat will burn the roots. The pots should be stood on the surface of the bed until the heat declines, when half plunging may be ventured upon. *Andromeda floribunda* makes a good showy subject for house-furnishing at a time when flowering specimens of stove and greenhouse plants are few. The bed usually accorded to Vines at starting time suits these shrubs well. If it is desired to have white Lilac, plants of Charles X. may be covered with boxes or even hampers with mats thrown over them.—J. C.

### MR. SANDER'S NURSERY AT BRUGES.

JUST on the outskirts of the quaint old Belgian town of Bruges and by the road that, between a double avenue of Poplars, leads to Ostend, Mr. F. Sander,

*Carnation Mrs. Reynolds-Hole in a pot. From a photograph sent by Mr. J. C. Smith, Nandana, Penrith.*

convenient house, such as is used for growing Cucumbers and Melons in, will do, provided the bed of leaves can be supplied, as when grown without a genial bottom-heat thus early in the year poor results generally follow. Lilacs may be flowered in a dark Mushroom house, but under such conditions the heads of bloom are small and poor. The earliest batches of the beautiful Ghent Azalea are better for a gentle warmth at the roots, and in January, Rhododendrons, Kalmias and kindred subjects used for standing in front halls or at the foot of staircases need the same rooting medium in order to secure the fullest development both of foliage and bloom. The well-known *Deutzia gracilis*, also the larger-growing single and double varieties, are quite at home plunged in a warm, moist vinery, a free growth being further encouraged by the spray from the syringe when the Vines are moistened twice daily. At the new year the red and white forms of flowering Currant force readily if bushes which

of St. Albans, is forming a nursery that promises to exceed in area and scope his well-known St. Albans establishment. At Bruges an attempt is being made to utilise certain local peculiarities of soil, situation, and climate to the fullest extent in the cultivation on an extensive scale of certain plants more or less always in demand. I lately had an opportunity of looking through the Bruges nursery, which has only been started about twelve months, and although it is at present in an unfinished state, there are tens of thousands of plants already happy in their new home, for as fast as any range or block of houses is finished the available space is immediately stocked. Orchids are a prominent feature of the place, not, however, from the point of view of rarity, but in the wonderful numbers of certain well-known species or varieties grown to meet the demands of the large cut-flower trade that is done in them upon the Continent. One house is entirely filled with *Dendrobium Phalenopsis*, and 10,000 ra-

cemes of bloom were all expanded at one time. This Orchid entirely fills one compartment of a long range, this division alone being 50 feet in length. They fill two central stages each 6 feet wide, two side stages, both more than a yard wide, are packed with plants, and numbers besides hang from the roof, whilst the flowers embrace every conceivable variation of colour that characterises this most graceful of Dendrobiums. *D. formosum giganteum* was also flowering in great numbers, the finer spikes having five and six flowers each. Cypripediums by the thousand were seen, also houses entirely filled with *Catleyas*, such as *C. labiata*, *C. Mendeli*, *C. gigas*, and *C. Sanderiana*. Another 50-foot compartment was filled with *Cypripedium insigne* forms, and *Oncidium tigrinum* was sending up hundreds of its bold flower-stems. Another block of houses devoted chiefly to *Odontoglossums*, but containing besides some other cool Orchids, had a roof of nine or ten spans, but internally the block was open throughout, thus admitting of a good circulation of air about the plants, which are arranged upon imperishable stages. There must have been many thousands of plants in this range. The stages are unique, simple, and, one might say, everlasting. Upon a framework of iron supported by iron legs, transverse bars of light T-shaped iron are laid at a sufficient distance apart to carry tiles of about 10 inches square and 1 inch in thickness, such as are used for tiled floors. These tiles rest upon the flanges of the bar on either side, and a durable, most efficient stage is the result.

Belgium, as is generally known, supplies most of the little *Azaleas* that come to this country bristling with flower-buds—*are forced*, go to market, and doubtless mostly perish afterwards. A seven-span block of houses was seen filled with these alone, the plants planted out on the benches. The *Azaleas* alone numbered something above 20,000. The largest houses are devoted to *Palms*, whilst others still larger are in course of erection for them. It would be useless to even hazard a guess as to the numbers in every stage, from the tiny seedling to the larger plants, in which trade is so regular and constant, that they are subject to no fluctuating variation of prices, but they are quoted *pro rata* according to the number of leaves they possess. *Latania borbonica* is the leading Palm, as it is one of the specialties of the Bruges district, and the houses have been specially constructed for its growth, with central tan beds in which the plants are plunged, whilst upon side stages other sorts are grown. Some of the future *Latania* houses, of which the walls are completed, have been made of sufficient width to admit of two plunging beds, with a central as well as two side paths. Other *Palms* noted in great numbers were *Kentia Belmoreana*, *Areca sapida*, *Areca lutescens*, *Cocos Weddelliana*, *Phoenix canariensis*, a magnificent lot, and the new and striking kind, *Bentinckia nicobarica*. One house contained many hundreds of *Araucaria excelsa*, this being a favourite pot plant on the Continent and one largely grown in this district.

An important industry round about Bruges is the growth of the Sweet Bay, the use of which enters into the social life and customs of continental nations to an extent that a visitor to these parts learns of perhaps with somewhat of surprise. I was informed that at the crowning of the late Czar of Russia, Bay to the value of £2000 was sent to that country, and it is calculated that more than double that amount will be expended in Bay at St. Petersburg alone next spring. It is calculated that there are one million Bays in the vicinity of Bruges, and although soil and situation favour its growth, the winter is too severe for the plants; consequently they are all grown in pots or tubs and lifted and stored in sheds or other cool airy places for the winter. There are old specimen plants about Bruges that are absolute heirlooms and have been in one family for quite half a century. Even artisans and others in no way connected with the gardening or the nursery trade grow Bays and seek to supplement their regular earnings. Mr. Sander likewise in-

tends to grow Bays largely, and a propagating house built specially for them was filled with cuttings, which numbered thousands, all nearly rooted without a single blank or failure. Within a fortnight this batch would be removed and another inserted. Even the trimmings of the trees that cannot be utilised as cuttings are a marketable commodity, always saleable by weight to use for flavouring or distillation.

A TRAVELLER.

### BEGONIAS AND SONERILAS AT ST. ALBANS.

Two classes of plants that Mr. Sander has latterly taken in hand and largely added to are *Begonias*, of which he has raised a set of handsome-leaved, free winter-flowering kinds, and *Sonerilas*, which have been greatly improved by intercrossing the two or three previously existing species. As regards the *Begonias*, Mr. Sander sought to get a race with the lovely leafage of the *B. Rex* type, combined with a freer flowering character than was ever manifest in any of the numerous varieties in this section of the *Begonia* family. In this he has been successful, and the progeny that has resulted from crossing *B. socotrana* with the *B. Rex* varieties shows a distinct advance in the right direction. Large groups of some of these varieties are gay in the St. Albans nursery at the present time. The influence of *B. socotrana* is apparent not only in the improved flowering qualities of the plants and the appearance of the blooms during the winter months, but the size of the leaves has been lessened and the habit of the plants greatly improved. The elegant shapes and varied markings in a beautiful harmony of silver and green are very marked in these new kinds, and above the leaves rises a profusion of spikes bearing flowers that in different kinds embrace soft shades of pink, pale buff, fawn-yellow and other tints. The following varieties we specially noted: *Winter Favourite* has pretty undulated leaf-edges; the centre of each leaf is of a silvery colour, which merges into a bronze-green, the outer zone of rich deep green being studded with pearl-like dots; its flowers are a light fawn-yellow. *Winter Perfection* is a gem, its leaves tinted with a silvery sheen, which forms a transparent tint overlying the deep green body colour of the leaf, the margin being bronzy red; its flowers of a distinct soft shade of creamy pink. Others equally charming are *Winter Beauty*, *Winter Charm*, *Winter Cheer* and *Winter Jewel*. Another set of plants Mr. Sander has classed as pillar *Begonias*, the characteristic feature being a tall habit of growth, which adapts them for training up pillars or for use in the several ways in which stove and greenhouse climbers are used. They would also make grand specimen plants grown on in large pots in the same way, for example, as we see *Begonia metallica* at Kew. In this state they would rival *Crotons* and *Dracænas*. In this set we made note of *The Queen*, quite shrubby in growth, with tapering leaves of a metallic red, the leaf-veins prominently picked out in deep green, the flowers coral-pink, disposed in large racemes. *Princess of Wales* is another superb kind, its leaves deep green, blotched with silver-grey and prettily spotted with salmon-rose, the drooping clusters of rosy pink blossoms in charming combination with the variously-tinted leaves. *Prince of Wales* has leaves of a sea-green, shaded with a glaucous tint and flushed with soft pink, the leaf-veins clearly delineated in green. *Duchess of York*, *Duke of York* and *Duke of Cambridge* complete this set, these latter three also most distinct in leaf colour.

The new *Sonerilas* are as beautiful as the *Anæctochilus*, with this advantage, that anyone who wishes can grow the former, not nearly so much skill being required nor are any special conditions needed beyond those furnished by a warm stove. These new kinds were as fine as the *Begonias*, improvement in them also being apparent all round in free growth, increased size and varying colouring of the leaves, and the brightness and profusion of their flowers during midwinter. Mr. Sander grows them in pots, pans and baskets. Some of them we saw suspended looked particularly pretty. Some of the best of these are *Silver King*, with stout, broad, silvery leaves and rosy pink flowers; *Victoria*, leaves quite 4 inches long, rich greenish bronze, with silvery centre, the margin metallic, green spotted with white and bearing rosy flowers in great abundance in crowded clusters. The leaves of *Mrs. H. Walters* are long, the deep green ground of these being veined with red and spotted white. In *Mr. H. Walters* the leaves are reddish green with white centre, white spots being distributed over the leaf surface, the flowers rosy pink, borne in amazing profusion. These two latter kinds received awards of merit from the R.H.S. last year. Besides those here mentioned there are nearly a dozen others grown at St. Albans all more or less distinct.

**Potting Lilies.**—I think it is now generally admitted that the autumn is the best time for repotting Lilies of the lancifolium section. As soon as the leaves fall I always cut the stems off the plants to within 6 inches of the base, and when this has partly decayed, repot in good holding loam, manure, free from worms, and a sixth part mortar rubble or road grit, draining the pots thoroughly and placing five bulbs in a 12-inch pot, merely covering the crowns. If the soil is fairly moist, no water is needed until growth commences in spring, and the pots may be stood in any convenient corner, not necessarily in the light, for the rest of the winter. Formerly Lilies of this class were usually potted when growth commenced in spring, during which operation it was impossible to avoid damaging some of the new roots.—J. C.

## PUBLIC GARDENS.

### CHRYSANTHEMUMS IN THE PARKS.

#### BATTERSEA PARK.

MR. COFFIN, the superintendent at Battersea Park, has provided in a large span-roofed greenhouse 110 feet by 25 feet a broad sloping bank of plants that have been in full bloom since early last month. Although every attention is given to the production of large flowers, yet the collection is here and there enlivened with the lighter and more artistic feature of bush-grown pompons and free-flowering Japanese, which lend a special charm to the exhibition. Varieties successfully used for this purpose are the well-known Golden *Mme. Marthe*, *Sœur Mélanie*, *Precocité* and *Sunset* in the first named section, while *Margot*, an old favourite, is employed in the other. A striking feature in the County Council Chrysanthemum shows is the number of high-class, old-fashioned sorts that are kept, and a visitor to the big societies' shows and the trade displays will find that many varieties once popular, but seldom met with in the ordinary way, will be found in the collections in the public parks. Additions of novelties are of course constantly being made, but it is evident that a rigid selection is exercised, and the result is that novelties are not added merely because they are novelties, but because they are really meritorious. Dealing with the older sections and taking the incurved first, it may be said that these are all well done—*Prince of Wales*,

Queen of England, John Salter, Lord Wolseley, Mr. Funn, Beverley, Alfred Salter, Geo. Glenny, Emily Dale, Jardin des Plantes, and many others well maintaining the reputation of the old show type set up forty years ago or more by the little band of Stoke Newington enthusiasts who were then unconsciously laying the foundation of the largest special society in the country. Some Anemones are grown, one of the best being M. Chas. Lebocqz, a pale yellow variety well known to exhibitors; Delaware, white and yellow, is also in good form. The reflexed section is represented by some good blooms of Dr. Sharpe, Cullingfordi, King of Crimsons, well known bright-coloured flowers eminently suitable for placing in large groups. The weird, fantastic Japanese of course at Battersea, as everywhere else, claim the premier position both in numbers and in colour. Vice-President Calvat is largely grown, and its massive crimson and gold heads of bloom are constantly recurring. Mme. Carnot, the fine new white Japanese, is also good, while Louise, received from the same raiser, proves its title to be one of the grandest introductions of recent years. Crimson varieties like J. Shrimpton, Gloire du Rocher, Beauté Toulousaine, G. W. Childs, &c., help to give tone to the Battersea collection and are judiciously interspersed with paler, but equally fine examples of cultural skill, such as W. Tricker, Etoile de Lyon, Viviant Morel, Puritan, Mr. A. H. Neve, Viscountess Hambleton, Mlle. Marie Hoste, Florence Davis, Eda Prass, Stanstead White, and all the other leading white and pinkish shades of popular Japanese. President Hyde, a rich golden yellow reflexed Japanese, helps to give tone to the group, and is dotted here and there throughout the whole collection, and that charming little pompon perfect in form, and always much admired, Mlle. Elise Dordan, is employed very usefully to lend variety to the blaze of colour so conspicuously sent forth by the blooms of the larger sections. Hamlet, an old favourite, a beautiful salmon-rose, seldom or never seen at the shows, is worthy of a note, and so, too, is Comte F. Lurani, often mentioned in THE GARDEN as valuable for this purpose. Lord Brooke, a deep golden chestnut, Miss Dorothy Shea, Mrs. Falconer Jameson, Val d'Andorre, Col. W. B. Smith are all of approximate tones when displayed in this way. Purple and amaranth shades are best found in such old favourites as Edouard Audiguier, which we have long regarded as extinct and were pleased to meet once more, not having seen its richness of colour and elegant drooping florets for many years, in A. Lunden, President Borel, and C. Sharman. J. S. Dibbin, a large yellow Japanese, and Source d'Or, always rich and attractive, are close to old Boule d'Or, whose heavily grooved florets and deep tone of yellow look rather greenish in such company. M. William Holmes is a valuable crimson intermediate Japanese for October displays. Le Verseau is a Japanese, most distinct in colour, being of a bright rosy pink, shaded carmine, and largely grown at Battersea for effect. Robt. Owen, Gloriosum, Mlle. Mélanie Fabre, a pretty dwarf pink Japanese, introduced many years ago, Mlle. Thérèse Rey, Charles Davis, Col. Chase, and some others of recent introduction all tend to interest not only the general public, who are said to have numbered something like 200,000 last season, but also the local grower who seeks to keep himself in close touch with the best novelties of the season.

#### SOUTHWARK PARK.

This park is situated in one of the most densely populated neighbourhoods of London, and the Chrysanthemums there under the charge of Mr. Curle prove the oft-repeated saying that the flower is pre-eminently a town flower. At the time of our visit there were about 2200 plants in bloom, although the number earlier in the season was greater by several hundreds. They are all very prettily grouped in a T-shaped span-roof greenhouse, a bank occupying the entire middle of the structure, with a narrow border of dwarf plants running round the sides, thus forming a path which leads the visitor back to the door from

which he entered. Palms, Ferns and fine-foliaged plants are nicely arranged amongst the Chrysanthemums, and climbing plants and creepers are trained at intervals under the roof, and when the Chrysanthemums are over the greenhouse containing them is rearranged with other subjects and kept open daily as a winter garden till the month of May. The approach has been widened, and consists of a broad gravel path, with rock-work mounds on each side studded with suitable subjects, and is an attractive addition. Here again, as at Battersea, the public flock in great numbers, as many as 9000 people passing through the house on a Sunday, and here, too, the Chrysanthemum fancier will find a wealth of material in the shape of good old standard varieties, although novelties at the rate of seventy or eighty per annum are added to the collection, which comprises a very large number of varieties in all sections. Fair Maid of Guernsey and Elaine are in good condition, and for white Japanese remained very long on the show-boards of our leading exhibitions. Condor, too, is still to be found at Southwark, although recent competitors for public favour, like Mme. Carnot, Mlle. Thérèse Rey, Rose Wynne, are vying with them for supremacy. There are other white Japanese like Mrs. J. Wright, Puritan, Mlle. Marie Hoste, Florence Davis, Florence Lierey and Stanstead White all in equally good condition, and many of the pale pink or lilac varieties have, now that the season has advanced, assumed a paleness of tint that would lead the uninitiated to class them in that category, viz., Good Gracious, Mme. E. Rey, M. E. A. Carrière, Louise, Mr. A. H. Neve, and the like. The Japanese mostly in evidence at Southwark, and remarkable for their fine blooms, are Charles Davis, Puritan, Louise, Gloriosum, Col. W. B. Smith, Wm. Seward, W. K. Woodcock and Edouard Audiguier, but beyond these there are some capital examples of Sunflower, the yellow Japanese, Richard Dean, crimson and gold, Miss Ethel Addison, Excelsior, Silver Cloud, Mme. Baco, William Tricker, Violet Rose and Viviant Morel. Golden Gate, a fine new yellow Japanese, is large and striking, and the golden yellow Duchess of Wellington, a fully-incurved Japanese, is too. Miss Maggie Blenkins and Lord Brooke, golden chestnut and belonging to the same section, are also large and fine. Boule d'Or, Val d'Andorre, Source d'Or and Robert Owen all attract the visitor's attention and need no description here. Richly coloured Japanese of purple or amaranth shades are found in Th. Denis, R. C. Kingston, a deeply-built Japanese incurved, Duke of York, Excelsior, Commandant Blusset, and others too numerous to mention individually. Then in crimson and crimson-bronze shades, Edwin Molyneux, still one of the most attractive, Wm. Seward, deep in tone and velvety, Cesare Costa, G. W. Childs, H. Jacotot fils, The Cossack, seldom seen now-a-days, and Joey Hill all add to the brilliancy of the display. In one corner of the building a curious and interesting group of hairy varieties, comprising about a dozen of the best of the type, are shown, the famous Mrs. Alpheus Hardy, white, Louis Boehmer, the pink variety, Prima Donna, King of the Hirsutes, Hairy Wonder, Sautel 1893, W. A. Manda, and Souvenir de l'Ami Coye being the best, all of them having on several occasions been fully described in the columns of THE GARDEN. Incurved are very numerous and well done: Lord Alcester, Miss M. A. Haggas, various members of the Queen and Rundle families, Baron Hirsch, Gloria Mundi, Hero of Stoke Newington, Violet Tomlin, Guernsey Nugget, Mr. Brunlees, Prince of Wales, Prince Alfred, the newer Chas. H. Curtis, finely formed and of a pure pale yellow, Mr. Jay, Lord Derby, the Beverleys, and others. Some reflexed, but principally the highly-coloured crimson Cullingfordi and the purple-magenta Dr. Sharpe, both of them introduced many years ago, are representative varieties. The large-flowering Anemone group comprise such standard sorts as Descartes, one of the most highly-coloured varieties we have, long ray florets and good disc of velvety vinous-crimson, speckled gold: W. G.

Drover, a self-coloured variety, pale rosy amaranth; La Marguerite, small, but very dark purple-amaranth in colour; Prince of Anemones; Fleur de Marie and Lady Margaret, both white and well known. It must be an inestimable boon to the dwellers in such a neighbourhood to have such a floral treat close at hand, and great credit is due to the superintendent and his assistants for the very fine display they have provided.

**Ipomœa rubro-cœrulea.**—The value of this Ipomœa recently alluded to in THE GARDEN is still further enhanced by the fact that it flowers during the autumn and winter months. Seeds of it are readily obtained, and if sown in the spring the young plants will grow away quickly and soon cover a considerable space. The temperature of a greenhouse suits it during the summer, but in the autumn and winter additional heat is required to see it at its best. There is a pure white variety, but the typical form from whence the specific name is derived produces blossoms of a charming, but almost indescribable shade of pale blue, that after expansion becomes suffused with red. As it grows freely and flowers profusely, this Ipomœa may be employed for draping the roof of a good-sized structure, and in this way it forms a charming feature. Where roof space is not available it may be trained around a few sticks, and thus form a bushy plant, and in this way a position may in most places be found for it. So treated the usefulness of the plant is to a great extent lost, but still it is very effective when studded with flowers, which succeed each other for a lengthened period. Rambling over twiggy bushes it is far more pleasing than if trained in any hard and formal manner.—H. P.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

DECEMBER 3, 4, 5.

The last show of the above society for the present year, which opened at the Royal Aquarium on Tuesday, was in all respects a most interesting one. There was good competition in all the classes provided, and perfect freshness was apparent in all the flowers shown. The largest class on this occasion was that for twenty-four distinct Japanese in not less than eighteen varieties, and the class was well filled, there being nine entries. The first prize went to Mr. A. Haggart, gardener to Mrs. Johnston Foster, Moor Park, Ludlow, who showed a stand of blooms that would have done credit to any exhibitor even at a November show. The flowers were remarkably fresh, the finest being Etoile de Lyon, Mlle. M. Hoste, Mrs. W. H. Lees, Le P. du Bois, Lord Brooke, Duke of York, Beauty of Castlewood, Golden Gate, Robert Owen, and Mons. Pankoucke. Mr. H. Perkins, gardener to the Hon. W. F. D. Smith, (Greenlands, Henley-on-Thames, was second, and Mr. W. Mease, gardener to Mr. A. Tate, Downside, Leatherhead, third. For twelve distinct Japanese, and with two more entries than in the previous class, Mr. A. Haggart was again first with a superb dozen, the second place falling to Mr. W. Messenger, gardener to Mr. C. H. Benners, Woolverstone Park, Ipswich, his flowers being remarkably fresh and clear in colour, but a little smaller. Mr. Haggart was again first for six Japanese, the second prize falling to Mr. J. Aplin, gardener to Mr. W. M. Baker, Hasfield Court, Gloucester. In the incurved classes, Mr. W. Neville, gardener to Mr. F. W. Flight, Cornisties, Twyford, Winchester, came in first for a dozen well-finished blooms, the best being C. H. Curtis, Mrs. R. C. Kingston, Lord Alcester, Mrs. R. King and Beauty. Mr. A. Haggart was second. There were eleven entries for six incurved blooms, Mr. H. Perkins being first with good blooms; Mr. W. Neville came second. In single varieties, twelve kinds, three blooms of each, Mr. G. W. Forbes (gardener to Mr. D. Nichols, Regent House, Surbiton) was first

with a fine lot, the second position falling to Mr. W. C. Pagram, gardener to Mr. J. Courtenay, The Whin, Weybridge. In small flowered singles, Mr. A. Felgate (gardener to Elizabeth, Duchess of Wellington, Burhill, Walton-on-Thames) was first with a pretty lot.

Some interesting classes on this occasion were those for flowers shown in trios in vases and with a good length of stem. For twelve trios of Japanese, Mr. R. C. Notcutt, Ipswich, was an easy first, with superb blooms of every kind, those deserving special mention being Duchess of York, W. H. Lincoln (improved and much incurved as shown here), Niveum (a graceful incurved white), Challenge, Robert Owen (very fine), Rose Wynne and Golden Gate. The second prize went to Mr. H. Alderman, gardener to Mr. G. Hatfield, Morden Hill, Surrey. A similar class was for six bunches. Mr. W. Slogrove (gardener to Mrs. Crawford, Gattin, Reigate) was first, three blooms of his new kind (W. Slogrove) being conspicuous here. Mr. T. Tullett (gardener to Mr. G. Alexander, Warley Lodge, Brentwood) was second. For twenty-four bunches of any varieties, Mr. H. Perkins was first and Mr. J. Applin second.

In the amateurs' classes, Mr. H. Love, Sandown, Isle of Wight, and Mr. E. Linfield, East Finchley, were successful in the order named for six distinct Japanese, and Mr. D. B. Crane, Archway Road, Highgate, was first for a large vase of Chrysanthemum flowers and foliage, Mrs. W. Green, Harold Wood, Essex, being second. There were eight vases shown in this class. Mr. Tullett, gardener to Mr. G. Alexander, Warley Lodge, Brentford, was first for six bunches of large flowered singles, and also first for the same number of small-flowered kinds, the second place in both classes falling to Mr. A. Meridew, The Gardens, Camberwell House, S.E. The St. George's Nursery Company, Hanwell, was an easy first for a collection of Cyclamens in pots, the second award going to Mr. J. McLeod, gardener to Mr. J. P. Morgan, Dover House, Roehampton. Mr. McLeod also showed the best dozen Cyclamens, Mr. W. Rapley, gardener to Mr. H. Grinling, Harrow Weald, being second. The best collection of Chinese Primulas was shown by Mr. A. Newell, gardener to Sir Edwin Saunders, Fairlawn, Wimbledon Common, Mr. J. P. McGregor, gardener to the Dowager Lady Hay, North House, Putney Hill, taking second place. Messrs. Newell and McGregor were similarly placed for a dozen Primulas, whilst the twelve best double-flowered Primulas and a charming lot came from Mr. W. Mease, Downside. Mr. W. Howe, gardener to Mr. H. Tate, Park Hill, Streatham Common, showed the best table of flowering, berry-bearing and fine-foliaged plants, a graceful arrangement of things in season.

#### MISCELLANEOUS.

Among the non-competitive groups that from Mr. Jones was the centre of attraction, and a charming arrangement of Chrysanthemums rising out of a groundwork of Ferns, the surface broken up with graceful Cocos and highly coloured Crotons, the group well finished in front with Crotons, Ferns and Isolepis. The gold medal given to this was a fitting award. Mr. W. Wells, of Redhill, had a fantastic arrangement of Chrysanthemums and foliage, also a number of stands and vases of cut blooms, embracing Japanese, incurved and decorative varieties in quantity. He received a silver-gilt medal. Mr. R. Owen, Maidenhead, received a silver medal for several stands of cut blooms, mostly new varieties. J. W. McHattie, J. Macfee and Ada Owen, Japanese incurved, were fine, also Robin Adair, the new Japanese Anemone variety, and Major Bonaffon was represented by three well-finished blooms. Messrs. H. Cannell and Sons, Swanley, showed a number of good varieties, notably Mrs. F. Thompson, Australie, Princess May, and Marjorie Hoffman, but a greater attraction by far and a welcome variation to the show was the grand lot of zonal Geraniums shown by the same firm. The exhibit comprised about fifty bunches well displayed above a groundwork of Maiden-hair Fern.

Some of the choicest kinds were Rosy Morn, Red Eagle, A. F. Wooten, Mme. Melba, Mme. Jules Chretien, Sea Gull, Lord Farrer, Lady Newton, Duchess of Devonshire, and Duchess of York, this last perfectly white. A silver-gilt medal was awarded. Mr. Norman Davis had a fine display of cut blooms, a comprehensive exhibit embracing all sections, a silver-gilt medal being awarded. Mrs. Filkins, Le Rhone, Rose Wynne, Tuxedo, Golden Wedding, King of Plumes, and Golden Gate were noteworthy in this exhibit. Mr. Godfrey received a silver medal for an exhibit of new and choice kinds. H. W. Rieman, Duchess of York, Owen's Brilliant, L'Amethyste, and Bouquettere were all charmingly shown. A large group of a dwarf and free-flowering white Chrysanthemum, useful for market work and shown by Messrs. G. Prickett and Sons, Stamford Hill, was awarded a silver medal. Messrs. Cutbush and Sons received a silver medal for a group of winter-flowering and fine-foliaged plants, and similar awards went to Mr. A. Meridew, Mr. J. Chard, and Mrs. W. Green, junr., Harold Wood, Essex, for table decorations. Vegetables from Mr. C. J. Waite, gardener to the Hon. W. P. Talbot, Glenhurst, Esher, were of fine quality, a silver medal going to this collection.

A meeting of the floral committee was held in St. Stephen's Hall, Royal Aquarium, on Tuesday last, Mr. T. Bevan occupying the chair. A large number of exhibitors presented novelties for adjudication, but there were no extensive displays, as at many of the previous meetings.

The awards made consisted of first class certificates to the following varieties:—

Mrs. C. E. SHEA.—A Japanese, with drooping florets, white, tinted sulphur. From Mr. A. Haggart.

GOLDEN DART.—A very attractive and valuable variety belonging to the decorative Japanese section, large in size, with long, flat florets, forming a starry-looking bloom; very free, and of a fine shade of pale golden yellow. An English seedling, raised and exhibited by Mr. E. H. Jenkins, of Hampton Hill.

KING OF PLUMES.—A small, decorative Japanese variety, a peculiar feathery-looking yellow flower. Shown by Mr. R. Owen.

Other novelties comprised some fine examples of Mrs. R. C. Kingston and Pearl Beauty, both considered to be too well known to be specially adjudicated upon; also Chamechaude, a violet-amaranth incurved of good form; Le Colosse Grenoblois, a large, globular Japanese, colour delicate rosy amaranth; and L'Amethyste, an incurved variety of a rich shade of violet-amaranth, which the committee desired to see again. J. W. McHattie, a fine crimson Japanese, was also asked to be shown on a future occasion. Several new American varieties—Mrs. W. Troy, The Egyptian, H. W. Rieman, &c.—though submitted in good condition, were passed over.

A meeting of the floral committee of this society was held on Wednesday, the 27th ult., at the Royal Aquarium, when Mr. T. Bevan occupied the chair. There was a good display of novelties, the principal collections coming from Mr. R. Owen, Mr. W. Wells, Mr. H. J. Jones, Mr. Weeks, M. Ernest Calvat, Mr. H. Briscoe-Ironside, and Mr. W. H. Fowler, J.P.

The following first-class certificates were awarded:—

W. SLOGROVE.—A large globular Japanese, rather loose in build and of incurved form; medium sized florets; colour deep golden yellow. Sent by Mr. W. Slogrove.

OLIVE OCLEE.—A Japanese incurved; florets of medium size, colour golden bronze, tinted purple. Exhibited by Mr. H. J. Jones.

SURPRISE.—This is a rather large Japanese Anemone, with flat ray florets incurving at the tips, good disc, a self-coloured variety, deep lilac-mauve. Also from Mr. H. J. Jones.

Mr. R. Owen was awarded a small silver medal for a capital collection of cut blooms arranged on boards and in vases. Bellem, a large rosy pink Japanese incurved, the committee wished to see again; also General Roberts, a large crimson-coloured Japanese. Mr. R. B. Martin, a long-petalled Japanese, yellow and carmine, and Miss Phyllis Fowler, a pale yellow incurved of good form, were also asked to be shown again. A similar request was made in respect to two of M. Ernest Calvat's seedlings, viz., Souvenir de ma Sœur, a large flesh-coloured Japanese, and Mme. J. Bernard, a deep rosy pink incurved Japanese. M. Demay Taillandier, crimson and gold, was large, but passed over. Songe d'Or, a rich yellow Japanese, very globular, was not considered distinct. Madeleine Davis is a large Japanese, with narrow florets of great length, pale rosy mauve, with a reverse of silvery pink. There were several other equally meritorious varieties, which will no doubt be presented on some future occasion.

## NOTES OF THE WEEK.

**Preserving the fruit of *Pyrus japonica*.**—Mr. Kingsmill, seeing that people were doubtful about making jam of the fruits of *Pyrus japonica*, has sent us a specimen of this jam. It is really excellent, and in our opinion better than the ordinary jam made from many small fruits, having a peculiar and distinct flavour. Inasmuch as this *Pyrus* fruits abundantly in some places, and people seem to think the fruits of little value, this information may be useful.

**An early Wallflower.**—We send for your inspection a few blooms of Earliest of All Wallflower gathered from plants sown as recently as last May. The plants have been flowering since the middle of September, and are still full of bloom and bud, and, should the weather not prove too severe, they will continue to yield acceptable gatherings throughout the winter months, bursting again into new vigour and beauty at the first touch of spring. The value of such a pretty spring flower in December must be apparent to all, especially growers for the market. The flowers are delightfully fragrant.—SUTTON & SONS.

**Snowdrops.**—Mr. James Groom (p. 430) in his note on these flowers suggests that they resent the proximity of the sea. I think that their failure to flourish with him must be attributed to some other cause than the sea breezes, as the scene of the engraving (p. 395) is considerably less than half a mile from the sea. I am also acquainted with a garden not many miles distant where the Snowdrops luxuriate in a wild garden that literally overhangs the salt water. Both of the localities mentioned are, however, sheltered, the former from all winds and the latter from all but the south.—S. W. FITZHERBERT, *Torquay*.

**Swainsonia Osborni.**—At p. 300 I wrote of the above plant under the erroneous name of *Swainsonia Veitchi*, and hasten to make the correction. The facts are these: My informant, who is generally pretty clear with regard to nomenclature, had for the moment confused the names of Veitch and Osborn in his own mind. The name *Veitchi* came so promptly, however, that I did not myself examine the label, or the error would have been discovered on the spot. It is also a singular coincidence that on my challenging the accuracy of the name the gardener in question perceived the error. As *S. Osborni* is included under *S. galegifolia*, it is quite possible, as surmised in THE GARDEN, that *S. Osborni* and *S. galegifolia alba* are synonymous.—E. J.

**Autumnal foliage.**—I never remember seeing such a profusion of richly tinted foliage as there has been this autumn. Although the very severe frost of the last week in October ruined some of the more sappy-leaved subjects, it really seemed to improve others. The common Beech, for instance, has been quite golden, so has the Tulip

tree, while many of the *Crataguses* have been remarkably beautiful. These last ought to be planted more frequently in parks or pleasure-grounds, nothing surpassing them for contrasting with the darker-leaved subjects. The leaves of the single *Pæonies* have coloured up more intensely than usual, and have been most acceptable for mixing with cut *Chrysanthemums*; in short, the whole of the above-named subjects are invaluable for the same purpose, and enable the gardener to reserve the various Ferns and trailers under glass for use later on.—J. C.

**Lasiandra macrantha.**—This, though an old plant, is seldom seen now, but there is none that can vie with it in its particular colour, a rich violet-purple, during the winter months. I lately saw a splendid plant covering 8 feet by 4 feet of a conservatory wall which was covered with blossom. The difficulty with this plant is to prevent its becoming bare on the lower portion, and only judicious stopping will avert this evil. With constant attention, however, its growth may be so supervised that the plant is well furnished from the base upwards. Sandy peat and loam form an acceptable compost, large plants, when once the border is well made, flourishing for years without requiring renewal of the soil. Small plants struck in the spring are very useful for conservatory decoration, forming a delightful contrast to *Begonias*, *Fuchsias*, *Geraniums* and the other summer occupants of the greenhouse. These young plants bloom at a height of 1 foot to 1 foot 6 inches, and produce their large, strikingly tinted flowers freely.—S. W. F.

**Canarina campanulata.**—A small plant of this singular Bellflower was exhibited at the last meeting of the R.H.S. The plant, however, was by no means a fair representative of this species, having only some three or four flowers open. To grow the plant well a rather liberal rooting medium is required, and if grown in a pot nothing short of a 10-inch or 12-inch one will do it justice. In such a size and in a warm greenhouse temperature the plant will soon cover a large space. It is best suited when trained near the glass. Loam, peat, and leaf soil in equal parts, one-fourth manure, and a little sand will suit it well so far as soil is concerned. The plant thoroughly enjoys a season of rest, and for this purpose, if convenient, it may be put out of doors when the growth is completed. Potting should be done as the growth commences, and at this time be careful not to over-water. When in full growth water may be liberally afforded, and weak liquid manure occasionally. Cuttings 4 inches long taken from the crown usually root freely in a dryish soil and not too closely confined.—E. J.

**Yellow-barked Willow** (*Salix vitellina*).—Planted close to the margin of one of the islands on the lake at Kew there is a group of this Willow. Cut back each year nearly to the ground, the stools send up a cloud of wands, whose bright yellow bark makes quite a bright and effective bit of colour, doubled as it is by reflection in the water. *Salix vitellina* is a British Willow, and, if allowed to develop, grows ultimately into a fair-sized tree. But when grown for the colour effect of its bark it is necessary to keep it in a shrubby state by pruning just before it commences to break into leaf. This should be done each spring, or at least not less seldom than every alternate one. Close by this is another Willow with red bark, also a variety of *S. vitellina*. A more extended use of these ornamental-barked shrubs in gardens for winter effect might very well be made. The red-barked Dogwoods (*Cornus sanguinea*, &c.) are very bright all the winter through, and in marked contrast to them we have several Brambles, among which may be mentioned *Rubus biflorus* and *R. leucodermis*, whose vividly blue-white stems are very conspicuous when devoid of foliage.

**Cestrum aurantiacum.**—When treated liberally at the root and given plenty of space for development overhead, there are few greenhouse plants which give a better return to the cultivator than this *Cestrum*. It is an exceptionally free-

flowering plant and for at least half the year may be had in bloom; it is also of very graceful habit. The flowers are borne at the ends of the shoots and are closely packed in large panicles, their bright orange-yellow colour being most effective against the background of luxuriant deep green foliage. Like all the *Cestrum*s and nearly allied *Habrothamnus*, this is one of the most easily grown of all greenhouse plants. It strikes as readily as a *Pelargonium*, and for a couple of years is useful as a shelf plant for the conservatory. It is so strong a grower, however, and requires so much soil and root-room, that its full beauty can only be developed when it is planted out in rich loam in a conservatory border. It requires support of some kind, and makes a very beautiful covering for the pillars of the house. It should be pruned back once a year, about the end of January preferably. A fine plant will grow to a height of 20 feet to 30 feet, but the species can be kept down to one-third those sizes by pruning, and is thus quite as well adapted for small as it is for large houses.—B.

**Notes from Oakwood.**—There is nothing remarkable to note about my *Lilies* this year. *Lilium auratum* was especially fine in rather damp soil in the wood and poor on the drier soil of the hill owing to the hot, dry weather. I think *Eulalias* are not enough grown; a good clump is always a pretty object; and when the autumn frosts cut the flowers that are out, *Eulalias* still show well for a time; besides the graceful leaves, the flowers make very pretty winter decoration. I bought some sent from Japan, not knowing what plant produced them till our *Eulalia zebrina* bloomed. This has flowered very well this season, and *E. gracillima* or *univittata* has had a few blooms with me for the first time. *E. japonica* has not flowered. I believe *E. zebrina* is the only one which can be relied on for flowers. The sharp frosts cut the *Liquidambar* a little; the leaves are beautiful, but not quite up to the usual colour. *Aponogeton distachyon* is flowering well. We have many *Primroses* and *Gentianellas* in bloom. *Iris Vartani* has been beautiful. *Gaultheria procumbens* clothing the side of ditches and on banks in full sun is always pretty, the red fruit taking the place of flowers. The North American *Cranberry* (*Oxycoccus macrocarpus*) at the side of a pond makes a pretty carpet, and the fruit is excellent stewed and in tarts—I think better, from being fresher, than the Russian *Cranberries*.—GEORGE F. WILSON.

**Daphne Mezereon.**—There is a little group of shrubs which even before the real winter commences give promise by their modest blossoms of its passing away, and the advent once more of spring and full floridite. Among these, and anticipating even the *Witch Hazels*, is the *Mezereon*, of which both the purple and white-flowered varieties are in bloom. The earliest flowering of all the varieties is *grandiflora*, which commences in early October; it is not only distinct in this respect, but also in having larger and more richly-coloured flowers. Balancing these advantages, however, is the fact that it never produces the profusion of blossom characteristic of the smaller-flowered ordinary kind, which, although opening a few buds from time to time all through the mild winter weather, reserves its full display for February and March. The plant is rarely more than about 3 feet high, although old specimens may be sometimes seen twice that height. The question whether the *Mezereon* is a true native of Britain is a moot point. It is, at any rate, truly wild in several parts of the country. As a cultivated shrub it has latterly been too little grown, for the beauty of its flowers, its fragrance, and its neat, compact habit recommend it to every lover of hardy shrubs. It is not a particularly long-lived plant, a fact which explains the neglect that has overtaken it, and also implies the necessity of renewing the stock by an occasional sowing of seed, which it ripens freely.

**The weather in West Herts.**—Last week was a very mild one. The night preceding

November 29 was especially warm for the end of that month, the thermometer in the screen never falling lower than 48°, which is about 4° higher than would be seasonable in the warmest part of the day. The exposed thermometer on the same night fell only to 47°—the highest reading recorded here during the previous ten years so late in the month. The temperature of the ground at 1 foot deep is now about 1° warmer than the average for the time of year. During the last eleven days of November the sun shone for altogether only about two hours, and on eight days no sunshine at all was recorded. The past month proved very warm—indeed, the warmest November for seven years. During the course of it there occurred only five unseasonably cold days, and but seven cold nights. Rain fell on nineteen days, and to the total depth of 4½ inches, or nearly 2 inches in excess of the mean for the month; the fall, however, was not quite so heavy as that in November last year. The rainfall for the last two months—which are the first two of the present drainage year—has been 7½ inches, or 1½ inches in excess of the average for this period. No sunshine at all was recorded on sixteen days during the month, and the average record only amounted to about 1½ hours a day.—E. M., *Berkhamsted*.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, December 10, in the Drill Hall, James Street, Victoria Street, Westminster. The committees will meet as usual at 12 noon. An election of new Fellows will take place at 3.

**National Rose Society.**—We are asked to state that at the society's Crystal Palace shows in 1896 and 1897 the following valuable prizes will be offered for Roses raised, or first distributed, by Messrs. A. Dickson and Sons, Newtownards, Co. Down, Ireland. There will be a class for amateurs for six distinct varieties, and another for nurserymen for twelve varieties. In each case the first prize will be a handsome silver cup and £2, second prize £2, and the third prize £1. Each silver cup must be won twice (not necessarily two years in succession) before it becomes the property of the exhibitor. The above prizes are presented by an amateur member of the society, who wishes us to make these classes known now, in order that intending exhibitors may be better prepared for them next year.

**Blue and yellow in flowers.**—At p. 371 A. Hemsley says: "It is remarkable that yellow and blue are rarely met with in the same class of plants. The Pansies are the only instance I can recall where the two colours are found." There are also yellow and blue *Columbines*, yellow and blue *Lupines*, and yellow and blue *Polyanthuses*.—M. D., *Edinburgh*.

**Mr. Barron's retirement.**—We have been requested to invite the attendance (as largely as possible) of members of the fruit committee at the last meeting of that body for the year, which takes place on Tuesday next at the Westminster Drill Hall. On that occasion Mr. A. F. Barron retires from the office of secretary to the committee, a post he has held for many years. We understand that a special proposition relating to that retirement will be made at the meeting. We believe the sense of the members is strongly in favour of Mr. Barron being placed on the committee by the council as a permanent member, as in that case his unique knowledge will be still available.

— We are pleased to learn that the council of the Royal Horticultural Society at their last meeting unanimously resolved to offer Mr. Barron an honorary life fellowship of the society, and invited him to serve on the fruit committee for 1896.

**Names of plants.**—*Desperandum.*—Please say how your Ferns are grown.

**Names of fruit.**—H. J.—Pear Maré Louise.

No. 1256. SATURDAY, December 14, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## CHRYSANTHEMUMS.

### OUTDOOR CHRYSANTHEMUMS.

WHERE a lot of cut bloom is required after nearly all outdoor flowers are over and there is not sufficient house room for a great quantity of Chrysanthemums in pots, plants of the decorative section that are throwing up strong shoots may be saved instead of consigning them to the rubbish heap and stored away in cold frames with a view to planting them in the open ground early in the spring. I used to make such a planting in autumn, but this is rather a risky business, as, despite a heavy surface mulching, many plants would succumb if the winter that followed happened to be severe. A warm corner must be chosen for the plants, and as the autumn protection of the blooms is an essential feature in this outdoor culture the plantation should be formed under an extemporised framework, over which stout tiffany or cloth can be easily placed in case of frost. The ground having been chosen, a bit of fairly good manure may be run on, and it can be deeply dug, or, better still, bastard-trenched at any time during the winter months. The shoots of naturally dwarf varieties may be thinned, allowing the strongest to remain, and in the case of taller sorts two or three of the stoutest shoots may be pinched back about the end of May and sturdy growths saved as they come away from the base, that is if it is desirable to have the plants of one fairly uniform height. Firm planting is essential, and if the ground has not settled down well a good treading is advisable before the plants are put in. If a good surface mulching is put on at planting time, the plants will not require any further attention until it is time to stake them, unless the summer prove very hot and dry, when one thorough good soaking will be beneficial. As the conditions of growth are naturally conducive to a stiff, sturdy habit of both wood and flowers, it will not be necessary to devote much time to the staking, just sufficient support being requisite to prevent the plants from blowing about. The advantage of a sheltered corner is always apparent, especially in those seasons when heavy gales are experienced just about the time the flowers are opening, in exposed situations the plants would stand a poor chance. A little thinning of the flowers is advisable to secure fair-sized blooms, and such treatment always tends towards the earlier development of the blooms, a highly desirable feature. Capital varieties for the purpose (the list may be largely extended) are Bouquet Fait, Hiver Fleuri, La Vierge, La Triomphante, Source d'Or, Maiden's Blush, Lady Selborne, La Adorable, and Jules Lagravier among older varieties, and of sorts only tried for the first time W. H. Lincoln, W. Stevens, Mons W. Holmes, Bouquet des Dames, Alexander Dufour, and G. W. Childs are very good. Jules Lagravier is with me the hardiest of all Chrysanthemums. Plants that stood out in the open for ten years succumbed at last to the cold of February, 1895. It may be noted that it is not advisable to plant late varieties out of doors in the majority of seasons, as the flowers will never develop satisfactorily. Spare bits of wall may also be utilised for occa-

sional plants. They can be easily protected, and will not fail to give a supply of flowers.

Claremont.

### CHRYSANTHEMUM GROUPS.

No one could visit Chrysanthemum exhibitions during last month without being struck with the decided change and improvement that were apparent in the appearance of groups of Chrysanthemums arranged for effect. Not only is there a decided tendency towards associating with the Chrysanthemum suitable fine-foliaged plants to give relief to the brightly coloured blooms, but there is a marked difference in the manner adopted to display the blooms. Instead of huddling the plants so closely together that each one lost its individuality, the plants in many instances were quite isolated, and thus produced a pleasing effect. The necessity of having dwarf plants well clothed with foliage and carrying blooms of high quality is becoming patent to exhibitors who wish to earn a reputation and win prizes. No doubt the grand object-lessons displayed at some few of the leading exhibitions, notably Hull, have had much to do with bringing about a better state of things in this direction. One of the prettiest groups of Chrysanthemums alone that I have seen was composed entirely of single and pompon-flowered varieties. Instead of the lumpy effect caused by crowds of large blooms packed closely together in one solid mass, the graceful single-flowered blooms gave a lightness to the group easily imagined amongst choice selected pompons. The group in question was at the Havant show the last week in October. The step which Mr. Jones took at the N.C.S. exhibition in November of employing fewer Chrysanthemums and adding choice, well-grown Crotons, Palms, &c., was a wise one, and will have a strong educational effect in time to come. The group in question was by far the best yet seen in the south of England. I notice, however, in many instances this season a tendency to employ too many yellow-leaved Crotons. When this colour is in excess, the harmony with the Chrysanthemum blooms is not good, especially when yellow so often predominates as it does in Chrysanthemums.

For years the Hull executive have encouraged the tasteful display of Chrysanthemums along with other plants by offering substantial prizes—a sure means of encouragement. Few societies have such a building as the Artillery Barracks in which to display their groups as this society. Very often the space is far too limited to give effect to the arrangements. Instead of the flat, sloping bank-like method of arrangement so common at some shows, the exhibitors at Hull, without exception, arrange their plants in mound-like groups, giving to the whole a series of undulations. For instance, a perfectly healthy half-specimen Kentia Fosteriana or K. Belmoreana will be raised on a mound from 3 feet to 6 feet high, the base covered with suitable fine-foliaged plants. Amongst these mounds the well-selected Chrysanthemums will be disposed. Every plant in the group, large or small, shows its own individuality; every part of it can be seen. By the aid of Moss and other greenery, all pots are hidden from view. Crotons with one stem, some 3 feet or more high, are displayed to advantage, especially when they are of the drooping character so suitable for decoration as is this section. By this method of arrangement the public are enabled to turn from the ugly, stiff, formal method of showing the cut blooms on flat, sloping stands of one uniform height and width, and thoroughly appreciate the more rational method of seeing this fine autumn flower displayed at its best. At York this style of grouping Chrysanthemums is meeting with much favour from visitors. Contrast these groups with those exhibited down the centre of the building in circular form, where no other idea seems to prevail except that of crowding as many plants as possible into a given space. Perhaps the executive are here somewhat to blame for confining the classes to so limited a space, which practically gives the exhibitor no alternative but

to pack the plants together as closely as possible to produce a bold effect.

At Hitchin one of the best groups of Chrysanthemums only was arranged that I have seen. The plants were quite dwarf, ranging from 18 inches to 4 feet. Each was beautifully clothed with foliage right down to the pot, and surmounted with blooms equal to any in the stands. Being thinly arranged, so that each flower could be distinctly seen, a grand effect was produced. Such an exhibit as this could not fail to be instructive. The Edinburgh show, although remarkably good in many respects, is lamentably weak in this department; not one single group arranged is worthy of an example for beginners to imitate. The plants are ill-adapted to the purpose in the first place, and secondly, the arrangement of them is very bad. At Norwich, too, I noted the same failing in an otherwise meritorious exhibition. At Leeds, where all other features are well displayed, the Chrysanthemum groups are simply sloping banks of plants with inferior blooms, except in two instances, where but a very few Chrysanthemums were employed. Some few years since the Chrysanthemum groups at Ascot were a credit to any society, now they are but third-rate examples. This depreciation is, I believe, mainly owing to a reduction of prize money. It is useless to expect merit where the return is inadequate to the labour expended. Many more instances of both good and bad grouping of Chrysanthemums might be given, but sufficient has been said to denote the decidedly improving tendency of displaying the Chrysanthemum in its best form. E. MOLYNEUX.

**Chrysanthemums at Swanley.**—I notice in the article bearing the above title on p. 414 a reference to a colonial variety called M. Van den Heede. This is a printer's error, but a very pardonable one. Van den Heede is a seedling raised by M. Ernest Calvat, but the one meant is Mr. Van der Heyde, a variety named after a gentleman at Strathfield, New South Wales.—C. H. P.

**A green Chrysanthemum.**—Several varieties of Chrysanthemums have been announced as having green flowers, but none of them have yet made their appearance on the show boards at our exhibitions. Unfortunately for the raisers, the colour is not an attractive one, although I believe such a curiosity would excite some degree of interest from the ordinary public. At the N.C.S. floral committee meeting of the 20th ult., M. Ernest Calvat staged a new seedling named M. E. Roger, which was a large-sized globular Japanese incurved variety of a peculiarly pale watery green shade. As shown, it might certainly find a place on the exhibition table, and the seeker after novelties should make a note of the variety, which will no doubt be distributed next spring.—C. H. P.

**Chrysanthemum L. Canning.**—Opinions may differ as to the excellence of this Chrysanthemum when compared with the now well-known Lady Lawrence, and probably some may prefer the latter. Those who require late blooms should, however, give L. Canning a trial, for it is undoubtedly an excellent kind for Christmas and the new year. With me it comes rather later than Lady Lawrence, the habit is more compact, and it is not so liable to mildew as most of the late blooming kinds.—J. C., *Byfleet.*

**Chrysanthemum Mrs. James Carter.**—We are now so inundated with so-called new varieties of Chrysanthemums that differ in the least possible degree, or perhaps not at all from others already in cultivation, that a good and distinct variety if it does not produce huge blooms is very apt to be overlooked, charming though it may be in some respects. Such an one is Mrs. James Carter, in which the florets are thread-like, and the bloom in shape a good deal after the manner of the yellow Sweet Sultan. It is in the catalogue of the National Chrysanthemum Society classed as a Japanese, but that is such an elastic term that it conveys little. The flowers are of a straw-yellow hue, becoming whiter with age. It is well adapted for growing as a bush, and is seen to the

best advantage when disbudding is very little, if at all practised, as then the clusters of light feathery flowers are infinitely more pleasing than many of the monstrosities that have only size to recommend them. Among varieties especially suitable for the greenhouse or conservatory this must certainly be included, although exhibitions innumerable may be visited without finding it represented. This latter remark will also apply to many other varieties particularly adapted for growing into bushes for the greenhouse and for cutting.—T.

### THE PAST CHRYSANTHEMUM SHOWS.

EXHIBITIONS of Chrysanthemums are all but over, and we may now look back and note a few things by way of observation. I think it can be said that Chrysanthemum shows were never so numerous as during the present year, and that the amount of enthusiasm was never more marked. This clearly indicates a liking for large blooms on the part of the public, whatever may be said about their ugliness and general unfitness for many purposes of decoration. There is also a greater number of amateur growers who appear to like the excitement of competition, and whose specimens bore evidence of careful culture. Many of the blooms, indeed, compare favourably with those produced by gardeners, who, of course, have better appliances.

The groups at the Aquarium were considered the best yet seen. This was due to fine-foliaged plants being intermixed with the Chrysanthemums and arranged with consummate skill. At many country gatherings I saw the same old style of grouping which exhibits anything but taste. The idea, apparently, is to tie each bloom to a stiff stick, and then to arrange the plants closely together with a surface as flat as a table. In finishing the front, too, there is an evident want of style when the pots and sticks are so naked to the eye. In pot specimens I have noted very little different from former years. The fine large trained specimens are more examples of unwearied patience than things of beauty. At one show there was a class for plants grown without disbudding, and only the necessary training to keep the branches upright. The first prize went to handsome bushes from which one might cut an armful of flowers without being missed. This appears to be a class that might well be extended in other directions. Such objects as the above Chrysanthemum bushes would be serviceable anywhere.

Undoubtedly the greatest interest is now centred in the cut blooms. Here the Japanese section is carrying all before it. In colours and varied forms there seems an endless variety, and better developed Chrysanthemum flowers than those exhibited during the past month of this popular class have not been seen in this country before. There is perhaps too great a desire to favour absolutely coarse varieties on the part of those who grow them, but the more refined sorts (not necessarily the smallest) are generally the more admired, the white *Mdme. Carnot* for instance. Is there any Chrysanthemum so beautiful? This variety has been splendidly shown. *Mons. Pankoucke*, *Mrs. W. H. Lees*, of extra size with grace of form; *Phœbus*, a splendid yellow; *Col. W. B. Smith*, grand in form and colour, and *Mlle. Thérèse Rey* have been very fine. *Charles Davis* and *Vivand Morel* are still two of the handsomest, and *G. C. Schwabe* is not yet surpassed in its shade of colour. *Eva Knowles* was most striking, the apricot hue being so distinct from anything else. A sort in fine condition was *H. L. Sunderbruch*, a lovely yellow. I have not seen the bright rose-coloured

*Mme. Marius Ricoud* so charming before. The incurved sorts, *Robert Owen* and *Lord Brooke*, were also abundant and handsome. Another sort of this shape, the pure white *Mme. Ad. Chatin*, was of remarkable beauty. Very few flowers of the popular yellow Sunflower came under my notice in the condition of former seasons, but *Thos. Wilkins*, a yellow, was remarkably fine in many instances. *R. Dean* and *M. Georges Biron* are two dark-coloured flowers with excellent qualities, and *Souvenir de Petite Amie* had few equals among white sorts. The pearly pink *Viscountess Hambleton* was not generally well shown, nor did I find many good blooms of the grandest of all dark Chrysanthemums, *Wm. Seward*. The above-named compose, of course, but a very few from the scores of varieties among the Japanese types; they are, however, of the highest excellence. Novelties in this section have been produced in large numbers. A few which will certainly be heard of again are the grandly-formed *Edith Tabor*, a yellow of a most lovely shade; and the handsome and massive shaded white, *Mrs. H. Weeks*. *Lago Maggiore* possesses a richness of yellow not seen in any other kind, and a fine light yellow is *Australian Gold*. *Dorothy Seward* (a terra-cotta shade) and *Mr. Herman Kloss* (an orange-shaded bloom) are great gains.

The prim incurved Chrysanthemums have been seen better. Many fine new kinds are coming to the front. *Chas. H. Curtis*, *Globe d'Or*, *J. Agate* and others have been consistently well exhibited. Anemone-flowered Chrysanthemums are curious, but there is a want of colour among them, and the pompons would, to my thinking, look better if grown with less disbudding. The charming single Chrysanthemums also lose their beauty by the rigid manner in which they are staged. I would like to see disbudding prohibited in the case of these; were they exhibited in sprays loosely arranged, their great beauty and usefulness would readily arrest one's attention. The value of Chrysanthemums for decoration might be seen again if more encouragement was extended to branches of blossom as grown without undue manipulation. These might be arranged in vases, and would assuredly prove attractive at autumn shows.

H. S.

## STOVE AND GREENHOUSE.

### CYCLAMENS AND PRIMULAS.

WILL any reader of THE GARDEN tell me how to have Cyclamens and Primulas fit for show the first week in November.—SUBSCRIBER.

\* \* \* Old corms, or those that have flowered once previously, of *Cyclamen persicum* can be grown into an extra large size the following season, but, as a rule, they would not bloom early enough to win prizes in November, nor are the flowers so fine as those produced from young plants. Sow the seed at once, but not broadcast; the better plan being to dibble it out 2 inches or rather less apart each way just below the surface, in pans of fine, light, loamy soil. A temperature of from 50° to 56° is quite high enough till the seed has swollen considerably, when a brisker heat is desirable. Keep the seedlings in a light position, and when large enough lift them out with a label and place singly in 2½-inch pots. Keep growing in a gentle heat and moist atmosphere, placing them on dry, hot shelves, a common enough practice, checking growth and hardening the corms, with the consequence that little or no further good progress is made. The 5-inch pot is a good size to flower them in. Some growers give an intermediate shift; others do not. When given a shift into 3-inch or slightly larger pots,

there is a chance of finally shifting a few of the very strongest into 6-inch pots. All ought to be in their flowering pots by the middle of July. A very rich soil is not desirable, but the aim should be to get the pots well filled with roots and then feel them. I use a mixture consisting of three parts of good fibrous loam to one of leaf soil, with a little charcoal, "burn-bake" and sharp sand added. During the summer the plants should be grown in pits or frames not far from the glass, and carefully shaded from bright sunshine. On bright days they ought to be occasionally lightly syringed or dowed overhead, and from first to last must never become very dry at the roots. This class of plants is liable to become infested with small green fly, which, unless kept under by means of either gentle fumigations with tobacco paper, or by dipping in tobacco water, soon ruins them. Flower them in a warm, somewhat dry house, not far from the glass, but avoid forcing or the leaves and flowers will become badly drawn. Pull no flowers from show plants after the first week in October, or the chances will be that not enough will be open when most wanted.

Old plants of Chinese *Primulas* cannot be recommended for exhibition. It is true they can be grown to a great size and produce abundance of trusses, but the flowers are under-sized and very frequently poor in colour. It should be "Subscriber's" aim to grow young plants to a great size, and have them in full bloom without subjecting them to a forcing temperature as this weakens them and spoils the colour of the flowers. Sow the seed in February or early in March, this being nearly or quite two months earlier than it is necessary to sow seed in order to have good plants for the greenhouse. Sow the seed on the surface of pots or pans filled with fine, light, sandy soil, and just press it in. Cover with a square of glass and Moss over. The seed will germinate most surely in a brisk moist heat. The soil must be kept uniformly moist without disturbing the seed, and before the seedlings become drawn gradually expose to the light. Keep them growing on a shelf in a temperature not often exceeding 60°, and when large enough pot off singly, using 2½-inch pots and sinking them well up to the collar of the plants, as it is scarcely possible to grow plants with a part of their stems out of the soil to a really serviceable size. Still keep the plants on a shelf in gentle heat, and when the soil is well filled with roots give a shift into 3-inch or slightly larger pots. After they have commenced rooting into the fresh soil transfer to a greenhouse shelf. In June or the early part of July their proper place will be on ashes in a shallow frame, and they should have a shift before they become root-bound. Some exhibitors are content to flower their plants in 6-inch pots, but occasionally they are gradually shifted into 7-inch and even 8-inch pots. The soil recommended for *Cyclamens* would suit *Primulas*, only if the loam is either heavy or devoid of root-fibres more leaf soil should be added. Make it fine for the young plants, but break up the loam into coarser pieces for the later shifts. Always allow each plant good room, abundance of sturdy leaves being a point in their favour, and ventilate freely, drawing the lights clean off on mild nights during fine weather. The central truss of flower is usually produced too early to be saved, but several extra strong later ones should be at their best in November. The plants ought to be flowered on a light greenhouse stage or, better still, on a swing shelf in a greenhouse, the colour of the flowers being further intensified by the occasional use of weak liquid manure, notably guano and that obtained from pigeons' or chickens' manure.—W. I.

**Well-grown Eucharis.**—This much valued flower is remarkably well grown at Hatchford. The plants are mostly in large pots, some of them exceeding 12 inches in diameter, and I counted as many as thirty flower-spikes in a single pot. The leaves are broad, of great substance, and of that rich lustrous green that renders the *Eucharis*, even when not in flower, distinctly ornamental.

It is not often that one sees such healthy specimens in pots of such large dimensions. Mr. Theobald is of opinion that many failures in the culture of this plant are caused by over watering, and that erroneous ideas prevail in this matter. In the case of large specimens the soil should become nearly dry before being moistened, thus preserving the roots in a healthy condition and to a certain extent guaranteeing them from the attacks of the mite. Cow manure, well sweetened, forms an important ingredient of the compost.—J. C. B.

**Acanthopœnix crinita.**—This is the plant alluded to on page 410 under the generic name of Acanthopanax, which belongs to a totally different subject, viz., a near ally of the Aralias. The Acanthopœnix is far better known as *Areca crinita*. It is a native of Seychelles, from whence it was introduced in 1868. The description, as given in THE GARDEN, exactly applies to this Palm, which, despite its high ornamental qualities, is never likely to become popular; as in the first place it is rather too lumpy—that is to say, the leaf-stalks are not sufficiently long to form a graceful specimen; next, the long, formidable spines detract considerably from its use for furnishing, and the foliage being thin in texture quickly suffers from exposure. Though the name of Acanthopanax does not occur in the "Dictionary of Gardening," the plant known as Acanthopanax quinquefolium variegatum has long been grown under that name in this country. In the just-mentioned publication it is referred to as *Aralia pentaphylla variegata*, the name of *Panax spinosum* being quoted as a synonym of the type; while in the recently-published "Hand List of Trees and Shrubs at Kew" the name of *Aralia spinosa* is given it, with *A. pentaphylla* as a synonym. This is certainly a fertile ground for confusion, as the old and well-known name, *Aralia spinosa*, is still retained; hence the difference in the specific names is only in the termination thereof.—H. P.

**Dracena lentiginosa.**—It is as well to bear in mind that the plant which has been recently exhibited under the above name is a variety of the well-known *Cordyline australis*, which is still frequently referred to as a *Dracena*. This particular form is also met with under the names of *C. australis atro-rubra* and *C. australis purpurea*, as well as that at the head of this note. The leaves are of a dull purplish brown hue, and not particularly effective, though they are certainly very distinct.—H. P.

**Heliconia illustris rubricaulis.**—This beautiful fine-foliaged plant alluded to on p. 416 must not be treated too liberally, otherwise it is apt to lose a good deal of its bright red marking upon which the principal beauty of the plant depends. When well coloured it is a grand object, but without the red veinings it differs little from the older, but rarely seen *Heliconia metallica*, and is by no means unlike one of the dark leaved Cannas. It requires stove temperature, and succeeds in a compost consisting of loam, peat, and sand, but if pushed on with occasional doses of liquid manure or some other stimulant, though the plant will readily respond to such treatment, the additional vigour is obtained at the expense of the brilliant colouring. This *Heliconia* can be propagated by division, the best time to carry this out being during the spring and early summer months, as in order to ensure the plants wintering well they need to be thoroughly established at that season. The older *H. aureo-striata* with the midrib and veins picked out with gold, though somewhat less vigorous, forms a good companion plant to the above.—T.

**Manettia bicolor.**—This *Manettia* was at one time more generally grown than it is now, though it is difficult to understand why such a charming plant has been allowed to almost drop out of cultivation. It is a native of the Organ Mountains in Brazil, and was introduced in 1843. A second species, *M. cordifolia*, is very pretty, but the contrast of red and yellow, which is to be found in the flowers of *M. bicolor*, is wanting in those of *M. cordifolia*, whose blossoms are of a

uniform bright red colour. Both may be readily struck from cuttings, and they grow away freely, if afterwards treated as ordinary greenhouse plants.—T.

## ORCHARD AND FRUIT GARDEN.

### THE MORELLO CHERRY AS A BUSH TREE.

How seldom the Morello is met with in gardens growing in bush form. This is rather surprising when its easy culture is taken into consideration. Apart from this, if so grown it would allow of valuable wall space usually devoted to growing the Morello Cherry being utilised for other fruits such as Plums, both for kitchen and dessert use. The Jefferson, Coe's Golden Drop, Kirke's, Pond's Seedling, and several other varieties succeed well on a north wall, and when so grown prove extremely useful where quantities of fruit are required late in the season. The Morello when grown as a bush is best worked on the Mahaleb stock, as the latter promotes a dwarf habit of growth, and the trees may be planted 9 feet apart. If planted by the side of a walk they should stand back 3 feet from the edge of the walk. The latter is the best site for the bush Morello, as it allows of the trees being netted over to preserve the fruit when ripe from bird attacks, and the washing of the trees, mulching of border, and other minor details can also be the better attended to. As is well known, the Morello prefers a soil inclined to be heavy, and the trees make the most robust growth and bear the finest fruit when afforded soil of this description, so that if not naturally present the staple should have loam of a heavy description mixed with it if light and sandy. On the other hand, very heavy soil is better if lime rubble is worked in with it when trenching it preparatory to planting, but it should not be overdone. Unless the soil is of a poor description, manure should be avoided, and then it should be thoroughly decayed and used sparingly, otherwise gross growths and gumming would ensue. A barrow-load or so of prepared soil would in all cases be preferable to the use of manure. The proper way to make use of manure is as a surface mulching after the trees have become established and begin to bear heavily, and they will then do with an annual dressing. It is astonishing how the roots find it and ramify in all directions, rendering the raking off of the remains of the mulch in the winter rather difficult to do without tearing the roots.

In a dry season the trees appreciate attention in the way of watering, and if this can conveniently be done finer fruit will be the result. Diluted house or farmyard sewage, although not a necessity, may be given with advantage. Little or no pruning is required beyond thinning the young wood when it has become at all crowded and removing dead branches. Stopping of the young shoots should be assiduously attended to during the summer months to prevent them from becoming long, bare, and straggling, and this stopping tends in a great measure to prevent gumming and loss of branches which generally overtake trees that are allowed to grow without any restriction. Stopping or topping of the shoots is best done when the young growths have about six or seven fully developed leaves.

Other minor details in their culture and which are the same as for wall trees are keeping the trees free from insect attacks, especially black fly, and if the latter gains a footing washing with an approved insecticide. If time

and labour will allow, an occasional wash with the hose where water is laid on or by means of the garden engine will help to keep them clean. As the washing of fruit trees during the winter months has now become recognised as an almost absolute necessity, the bush Morello should also receive attention in this direction, and even if nothing but soap-suds is used two or three times while the trees are in a dormant condition, there will be little to fear from an insect attack the following spring.

On bush trees the fruit will hang in perfection until the end of October or nearly as long as that grown on a wall, and in point of quality, size, colour of fruit, it is equal, while there is a considerable difference in favour of the bush tree in the cost of production. A. W.

**Sparrows and Gooseberry buds.**—In most gardens sparrows are more or less troublesome amongst Gooseberry bushes, various remedies being adopted to keep them at a distance. Some gardeners defer pruning till late in spring, thinking that thereby a greater percentage of buds will be spared, and that then the pruner can judge better how to use the knife. In very large gardens, however, containing many bushes this postponement cannot be indulged in, as work is usually very pressing in spring, to say nothing of the check given to the trees by wholesale shortening of the branches when in this advanced state. My experience is that if the trees are pruned even in November, sparrows and bullfinches may be kept away by sprinkling lime and soot over the bushes every three weeks during showery weather. Wood ashes are very effectual, as being bitter the birds do not like them.—J. C.

**Pear Black Achan and others.**—This Pear (Black Achan) is not so commonly met with in Scotland as it was many years ago. I notice it in some catalogues, however, and it is described as of excellent flavour. It is not a handsome Pear, but some of the best Pears, and other fruits, are poor in appearance. I only remember this Pear as a free bearer on a low stone wall while I was a youth under my father's tuition. I have never seen this old favourite so fine as on some old houses in Scotland, and where gravel walks were formed over the roots. The finest dish of Doyenné du Comice I ever saw was at Glasgow show (November 21). They came from Lord Hamilton's gardens, Dalzell, and were among some other fine examples in the first prize collection.—M. TEMPLE, Carron, N.B.

**Caterpillars on fruit trees.**—After the note at page 419, perhaps you may like to see a band which has been in operation. The one sent has on it about 130 insects (mostly females) of the winter moth, and therefore representing a vast number of eggs, and later on of caterpillars. The moths have been in great force this season; many thousands have been caught. The band was cut in two in order to get it into the box. We use a band of the Willesden brown paper next the trees and the canvas over it. The canvas will serve for some years if cleaned from grease by beating it, and putting it by. Perhaps I should add that Oakwood garden appears to be especially attractive to the winter moth. Some years ago we banded the trees in our two gardens at Weybridge, when so few moths were caught that it was not necessary to continue the precaution.—GEORGE F. WILSON.

**Pruning Peach trees.**—I quite agree with J. C. Clarke as to the advisability of the early pruning of Peach trees. I never could see the wisdom of leaving this over till the early spring or just preceding the buds advancing into colour. Personally, I never have any set time for such work, it being a matter of when the time can be best spared after the leaves fall. Sometimes it is early and sometimes later. Trees that have been carefully disbudded, so that there is no overcrowding of shoots, and which also have had surplus shoots cut out after the trees are cleared of

fruit, cannot possibly receive any harm by early pruning. Under glass I prune as soon after the leaves have fallen as possible; the branches and shoots being cleaned at the same time. These are tied in as soon as time can be spared. The wood of open-air trees if it is ever killed or injured by frost must be in a very indifferent state of ripeness, and such trees could never be expected to produce satisfactory crops of fruit.—A. YOUNG.

**Strawberries for forcing.**—I cannot quite agree with Mr. G. Wythes regarding early forced Strawberries in your issue of December 7. I, like him, am no advocate for early forcing merely for the sake of having forced fruit. Mr. Wythes relies upon Vicomtesse Héricart de Thury for his earliest supply. I must differ from him, for where one has to keep up a daily supply for the dessert from the middle of February onwards he cannot do better, I think, than give La Grosse Sucrée a fair trial, it being, I find, the most prolific, well-formed, best flavoured, and solid fruit for packing. It will stand hard forcing, as I have 200 plants showing flower at the time of writing. I use Vicomtesse Héricart de Thury but little, and that for a second early as the flesh in travelling becomes somewhat insipid. To follow this one cannot have a better in this district than Captain (Laxton), the flavour being good, the fruit also travelling well. As a succession to this little grown variety I use Sir Joseph Paxton.—JOHN T. HAYES, *Castle Ashby, Northampton.*

**Late Plums.**—W. G. C. (page 390) advises the culture of Wyedale, and those who grow for sale will find his remarks valuable, as this variety follows Monarch, a much finer Plum I admit, but size is of less importance when fruit is wanted much later than Monarch will provide the supply. At page 429 Wyedale is highly recommended for cooking, and I quite agree with Mr. Neighbour's remarks. With me it has never failed to give a crop. My trees are all standards, with a short stem, and the fruit is of fair size. I was not aware Wyedale had been in cultivation so long. I have only grown it a few years, in fact was unaware of its existence till I saw young trees cropping freely in the Maidstone district. I may also add I saw some grand young trees in the autumn of 1889 in the South of Scotland, in poor land and the variety was thought much of on account of its free cropping qualities and for preserving. At page 419 J. C. notes the value of the old Winesour Plum for late use. This is certainly a valuable variety in districts where limestone abounds, but I have grown it on a thin sandy soil and rarely got a crop, but this was in the southern part of the country. In northern districts it was the reverse, and much liked for cooking, keeping good when gathered, well through October and November. Late Rivers is an excellent late Plum for dessert. I do not notice this variety is recommended. I find it invaluable for late use, and though not large the flavour is good for so late in the season, and it may be had in November. Coe's Late Red is valuable for October dishes, but with me not so good a cropper as the Golden Drop. The kinds named by Mr. Neighbour do not crop so well as I could wish, but, as stated, they are fine late varieties and in a good fruit soil are valuable when grown on walls, as they bear more freely and are easily protected.—W. S.

**Cider making.**—This industry appears to be growing, and this fact will, I think, prove in time a boon to those who grow Apples for market. In abundant seasons when, during October and November, Apples are a glut on the market, second quality samples do not pay to send to towns at a distance, even if conveyed by cart or van. But when sent by rail and handled by a salesman, the grower often finds himself out of pocket in the end. What then becomes of tons of small and inferior fruit in districts where no cider factory exists? They are thrown to the cattle or allowed to lie and rot. In Norfolk one large manufactory already exists, which it may be reasonably supposed will use up all samples that cannot find a ready sale in the ordinary market, and if the

price given is small, it will help to pay for labour. I heard recently that the large Kentish growers thought of combining to establish a cider factory, and I should think the experiment would succeed, as in seasons of superabundance, not only the smallest, but large quantities of medium sized, average quality fruit would be available for cider making. Thus the quality would be superior, and the vast metropolis being so near at hand a ready sale for such a wholesome drink would be ensured. I am told that in the cider counties of Worcester and Herefordshire farm labourers prefer it to beer in hay time and harvest.—J. C.

#### THE WINTER MOTH.

ACCORDING to present indications, next spring will witness a very violent attack of the larvae of the winter moth not only on fruit trees, but also on forest trees, hedgerows, &c. In pruning Apple, Pear, and Plum trees recently a far greater number of the practically wingless females has been discovered than is usual, and the eggs are much in evidence about the buds, in the forks of the shoots, and at the ends of those shoots that have been pruned. The latter is a very favourite place for egg-depositing, the female cleverly fixing the eggs between the bark and the wood in the slight cavity usually found after pruning. I have on many occasions counted over seventy eggs at the end of one of these cuts, and when this goes on all over a tree, almost every egg hatching out its caterpillar, it must be plain that the attack will be very serious indeed; and unless the tree is very vigorous and, thus to some extent able to withstand the pests and their ravages, the consequences are most likely to be extremely serious. Most of our entomological authorities state that each female will deposit 200 eggs each, but, so far as I can learn, they do not state if more than one batch of that number is laid. From some experiments made, I feel sure that several similar quantities are laid by each female during the season for laying, which continues from early in October to the end of February, and occasionally later. If one of these female moths is restricted by means of very fine netting to a limited area, with facilities for depositing her eggs, it will be found that fully 200 have been laid in five days, and, unless my experiments have been wrong in some way unknown to me, this female if allowed freedom, but prevented descending from the branch on which she has been a prisoner, will in about three weeks be ready to lay another batch of eggs. In face of this enormous deposit by the large number of moths, it may be asked, what are the best means to adopt to render the threatened attack as light as possible? The first and most important is to thoroughly cleanse the trees of all Lichen, mossy growths, and other filth, by means of some of the recipes advised in THE GARDEN from time to time. One of the best of these cleansers for all dwarf-growing or wall trees is, 1 lb. of crude potash and 1 lb. of caustic soda, dissolved in 10 gallons of hot water and applied warm to every portion of the trees in the form of a spray. This is a splendid winter wash for fruit trees, but it should be understood that it will not destroy the fertility of the eggs. No insecticide or tree wash will do that without first killing the trees; therefore the remedy would be worse than the disease. Its usefulness is, that by killing and fetching down Moss or filth from the branches, thousands of eggs are dislodged, and by falling down to the soil they fail to hatch out on such an unsuitable medium. With tall standards the

spraying with the above mixture would be so difficult to apply over the higher branches, that it is impracticable, and other measures must be adopted. One of the best modes of dealing with these tall trees is to procure some fresh air-slaked lime and throw the same over the branches when the Lichen is a little damp. A handy-man with a ladder will soon do a lot of trees if he has another to wait upon him with lime as he requires it. By the above methods, thousands of eggs of this winter moth will be dislodged and destroyed, as on examination it will be seen that immense numbers of eggs have been laid in the mossy substances on the branches. When there is no further danger of more eggs being deposited, say in March, it will pay for the time and trouble to go over all the dwarf trees, and cut a small piece from the end of former cuts, taking care to put each piece in a basket or box as it is cut from the tree so that all may be burned, thereby effectually disposing of a great number. Anyone with good eyesight can easily detect the eggs in the positions mentioned. When first laid they are nearly white in colour, gradually changing to almost an orange hue, which colour they retain until they are hatched. W. G. C.

**Keeping Apples in boxes and barrels.**—There seems to be a general inclination amongst amateurs and gentlemen to have their Apples packed in boxes and barrels, with an idea that they will keep sound for a longer period, fresher and with less shrivelling than on the shelves of the fruit room. While admitting there is a certain amount of truth in the above, there is another point which people probably fail to recognise, viz., the depreciation in the flavour, especially in the finest-flavoured dessert varieties like Cox's Orange Pippin, Roundway Magnum Bonum, Ribston Pippin and others of that class. Cooking varieties are also affected, but it is no observed so much owing to the cooking. These whose tastes are cultivated quickly detect the loss in quality, and those who contemplate storing in the above manner should bear this in mind.—W. G. C.

**Starting early Vines.**—While many ignore the old-fashioned plan of forming a ridge of sweet new Oak and Beech leaves on the floor or border of early vineries, I have still great faith in it; in fact, I think that where this can be done there is no need for syringing the rods at all, as the healthy vegetable ammonia given off by the leaves is just what is wanted to induce the eyes to break quickly and well. Not only is the insecticide mixture soon washed off by frequent syringings, but much harm results from soaking the rods in dull cold weather, especially when by afternoon syringings they remain wet all night. I am certain that mildew and a host of other evils are brought about by this process in early forced vineries, and for that reason I never wet the rods in the afternoon, except in fine bright weather.—J. C.

**Gumming in fruit trees.**—Although the causes of gumming in all kinds of fruit trees are manifold, yet one of the most fertile is that of allowing the ligatures to cut into the bark and even inner flesh of the tree. Many who plant fruit trees are not aware that much mischief may be wrought, even in a single year, by allowing insufficient room for bark expansion. I have sometimes seen the wire, by which the labels have been fastened to the trees, all but buried in the wood, defying all endeavours to withdraw it. The best way is to fasten the labels to the wall by means of nails, and not to suspend them from the trees, as is frequently done. All ligatures should be examined annually, and where the least pressure exists, replaced with new ones. In tying Peach trees it is far better to brace the shoots with twisted matting than to endeavour to straighten them by too tightly tied ligatures.—J. C.

## WILTON HOUSE.

THE visitor to Wilton who has no previous knowledge of the town's history, but knows it chiefly through its far-famed carpets, learns with some surprise that this quiet old town has an illustrious past. It was at one time the chief town of the Anglo-Saxon kingdom of Wessex, whilst later on it gave its name to the shire in which it stands—hence Wiltshire. Its period of greatest prosperity was from the ninth century onwards to the year 1244, in which year the Great Western road was diverted, and from thenceforward its prosperity waned. Here, too, was once an important monastery, given to Sir William Herbert, first Earl of Pembroke, by Henry the Eighth, and on, or near, the site of this monastery now stands Wilton, the Earl of Pembroke's charming seat. Although close to the town, so well timbered are the surroundings, that the mansion stands in perfect seclusion, looking out upon a scene in which the combined beauties of Grass, water, and trees abundantly compensate for the somewhat confined area

feet up to the point of branching and of fairly even diameter throughout its length of main stem, which girths fully 24 feet. A stem of greater girth entirely enshrouded in Ivy stands near by, the tree having perished in a storm some years ago. A noble evergreen Oak near the Cedars next arrests attention. The stem girths 19 feet, and at one time it had a symmetrical rounded head of branches spreading quite 100 yards in circumference, but a giant Cedar in its fall broke away a large portion of this Oak on one side. It is a magnificent specimen in perfect health, and bids fair to grow out of its present disfigured state. Near this tree, and on the west side or library front of the house, is an Italian garden, and beyond it a long vista terminated by a stone structure called Holbein's Porch. A fine *Chamerops Fortunei* stands near, this also being a plant out of the first introduced batch. It has been outside for seventy years, is not so tall as some younger specimens we have seen, but its stem is unusually thick and denotes great age. A

Looking eastwards from the house, the ground stretches away almost as flat as a table, but this flatness has been delightfully broken up by a series of admirably arranged groups, chiefly of coniferous or evergreen trees and shrubs margined in a pretty way with graceful masses of *Savin*. A broad gravel walk at right angles to the east front of the mansion, with lawn and fine trees on either side of it, extends for 300 yards, and is terminated by a seat hedged round with *Yew*, and near it a trio of fine trees command admiration in *Lawson's* and the *Nootka Cypress* and *Thuja gigantea*. On the opposite side of the walk is a fine group of *Pinus excelsa*, the trees large and laden with fine cones at the time we saw them. This bold walk and the shrub groups that break up the flatness of and give distance to the fine expanse of lawn that extends to the water-side are from the designs of Sir Richard Westmacott, who assisted the Countess of Pembroke in greatly beautifying the grounds.

The second engraving shows well that portion of the house commanding the view of this broad walk, with its adjacent lawn and distant water, whilst between the trees in the distance is seen the tall spire of Salisbury Cathedral. Near the river a statue of *Venus* on the top of a column stands in the centre of a little square formed by trees of the *Italian Cypress*, which have to be renewed from time to time as they fall, but there is one tree—differing in no outward appearance from its fellows, and apparently growing under like conditions—that seems altogether hardier and more robust. It weathered the winter of 1860 when all the others were killed, and it is still quite healthy. The red Cedar was charming in some of the groups, its branches laden with glaucous fruits, that appeared as a silvery sheen cast over the tree. *Yews*, *Hollies* and *Evergreen Oaks*, numerous and fine, give perennial verdure to the grounds. Coniferous trees in sheltered breaks and nooks are equally luxuriant, a tree of *Picea cephalonica* especially so, being nearly 100 feet high; whilst many more of this tribe are growing with a vigour that betokens the congenial conditions of soil and situation. These trees have been planted by Mr. Challis, who has had charge of these gardens more than thirty years.

The fruit and vegetable departments alone merit a detailed notice, but our visit was at the end of the season, after the ingathering of the crops. At any time of the year, however, the visitor could not fail to notice the grand pyramidal *Pear* trees that margin the vegetable quarters, all of which have been planted and trained to their present perfection of form within the period of Mr. Challis's charge. The fruit walls are equally well clothed, *Peaches* and *Figs* having the protection of a broad coping overhead. Under glass there was the same evidence of good all-round culture, particularly visible in the *Grapes* that were still hanging, one house especially, filled with *Venn's Black Muscat* alone, of which the crop was almost intact, the bunches individually ranging up to 4 lbs. weight. The back walls of the *vineries* here are also covered with *Vines*, and *Alicante* gives some really serviceable bunches under conditions that many would hardly expect them. In the *Peach* houses, too, quite a different method of growing the trees has been adopted, and Mr. Challis claims to get three times the amount of space, with the crop, of course, in proportion. The front trellis of the *lean-to Peach* houses is not run longitudinally, but instead there are transverse trellises with trees on either side of them. This also allows of trees being fruited on the back walls of the house, and the best answer to any question that might be raised as to the value

Wilton House, south front Engraved for THE GARDEN from a photograph by Mr. S. Griffin. Lucerne, Wilton Road, Salisbury.

within view. The mansion stands near two rivers. The larger one, named the *Nadder*, bounds the garden grounds in front, and a smaller stream, the *Wily*, separates the kitchen garden from other portions of the grounds, both ultimately mingling their waters and flowing on to join the *Avon*. The mansion is of stone, its earliest portion being from the designs of *Hans Holbein*, but the greater part of it was designed by *Inigo Jones*.

One of the great glories of Wilton is its fine *Lebanon Cedars*, the tree having been extensively planted here at the time of its first introduction, and although later years have witnessed a great thinning of its ranks, enough remain to form the most prominent feature of the place. The *Wilton Cedars* are older than those at *Goodwood* or *Warwick*, and although mighty ones have fallen, some still remain, whilst numerous young ones are growing up to take the place of those that fall victims to the storms. Whilst the present wise policy of frequent planting is continued, there will be no break in the history of this tree at Wilton. The finest old specimen has a grand bole about 15

feet up to the point of branching and of fairly even diameter throughout its length of main stem, which girths fully 24 feet. A stem of greater girth entirely enshrouded in Ivy stands near by, the tree having perished in a storm some years ago. A noble evergreen Oak near the Cedars next arrests attention. The stem girths 19 feet, and at one time it had a symmetrical rounded head of branches spreading quite 100 yards in circumference, but a giant Cedar in its fall broke away a large portion of this Oak on one side. It is a magnificent specimen in perfect health, and bids fair to grow out of its present disfigured state. Near this tree, and on the west side or library front of the house, is an Italian garden, and beyond it a long vista terminated by a stone structure called *Holbein's Porch*. A fine *Chamerops Fortunei* stands near, this also being a plant out of the first introduced batch. It has been outside for seventy years, is not so tall as some younger specimens we have seen, but its stem is unusually thick and denotes great age. A

flight of steps from the Italian garden leads up to an orangery filled mainly with *Camellias*, large and small, in pots and planted out, all in perfect health. The view here given is that of the south front of the house, showing a little garden of stone-edged beds set in gravel. Beyond, adorned only by the grand trees on it, the lawn spreads away to the river bank, the river itself being spanned by the "*Palladian Bridge*," built of stone and having a roof supported by rows of columns on either side. This leads to the deer park, in which the ground rises upwards to a considerable elevation, whilst along this slope another informal avenue of *Lebanon Cedars* is a fine feature amid the great beauty of native trees in abundance and of large size. An interesting fact gathered in regard to the *Cedars* is that on an average once in ten years they ripen a good batch of seed, and advantage is always taken of a favourable opportunity to save some and sow for future planting about the place. The past season had been a suitable one, and numbers of fine cones were seen well advanced towards maturity.

of the practice is, that it has been followed a number of years, and no necessity has arisen to change or modify it. A range of what once was Pine pits is now filled with a varied collection of Orchids, *Cattleya labiata* being finely in bloom at the time of our visit. *Chrysanthemums* in great numbers filled another long house, every plant grown on more natural lines and allowed to give sprays of many blossoms. We also saw a delightful display of this flower outside the houses. The plants are grown in narrow borders along the fronts and ends of the houses, and trained loosely to the brickwork. They have night protection with canvas, which is removed by day, and many graceful Japanese kinds not tried, as a rule, outside were flowering admirably.

## KITCHEN GARDEN.

### THE BEST TOMATOES.

PROBABLY there is no kind of fruit or vegetable grown on which there is such a difference of opinion as to which is the most productive, best shaped, and of the highest value for market as in the case of Tomatoes. Take any dozen growers and ask which variety they consider the best, and at least ten of the replies will be different; some of them will state they have one of their own that has been hybridised and selected annually from the handsomest fruit and most prolific plants until, by the exercising of great care they have at last got a variety equal to any in commerce. This answer has frequently been given me during the last few years, and if I were questioned on which I thought was the best I had grown, my answer would be much the same. There is no doubt varieties of Tomatoes degenerate considerably unless precautions are taken in the selection of the fruits and plants for seed; therefore to avoid growing a poor and possibly unprofitable sort many growers cross or select their own seed from the best of the proved varieties they have. Amongst the host of so-called distinct Tomatoes there are not many sorts much better than Conference, as it combines robustness with a very prolific habit. Some object to it that the fruit is scarcely large enough, but the taste for big Tomatoes is passed by both for use in the kitchen or for market. A fruit that weighs a quarter of a pound is quite large enough, and is now much preferred by all Tomato eaters. Duke of York is another variety that will probably be much more extensively grown in the future, as its merits are becoming highly appreciated. If no thinning of the fruit is practised, the size is just what it ought to be for selling, averaging about three or four to the pound; the shape is perfect, also the colour, and the flavour all that can be desired, with the further advantage of the plants bearing freely for a long period. As an exhibition variety it is also valuable. By thinning out the fruit to two or three in each cluster and supplying the roots with plenty of suitable plant food, Tomatoes over 1 lb. each in weight will be produced, of model form and lovely colour, very difficult to excel by any other variety. Sutton's A 1 is a great favourite with some growers, as it bears a heavy crop of moderately sized fruit of good shape and deep colour fairly early in the season. I have grown this sort extensively both in pots and planted out in firm shallow borders, it succeeding well in both, but it appears to give the best results from pot plants, my average being 14 lbs. from each pot (10-inch). Of all the early varieties that I have tried none has been equal to Early Ruby for

first supplies. The rapidity with which this comes into bearing, its great cropping powers at a time when Tomatoes are most valuable, and the good quality of the fruit make it a decided acquisition. Although Early Ruby is a comparatively new variety, selection is desirable, as unless this is done many of the fruit come of irregular form, and are not so much in demand by fruiterers and greengrocers as those of better shape. I believe the days are gone by for growing the corrugated varieties for market; they may be satisfactory for home use, but buyers of all grades now prefer Tomatoes of good shape, and the majority of growers recognising this fact only favour those varieties possessing that qualification. W. R. H.

**Horse Radish.**—Happening to refer to the fact that the Dutch supply our Christmas markets so largely with Horse Radish—which we should be able to grow ourselves equally as well—at the close of Mr. Mason's lecture on "Asparagus Culture" at the Drill Hall on November 20, I was much interested to learn from Mr. Mason, who is an experienced market man, that the public greatly preferred the Dutch roots of Horse Radish, because so much less hot or milder than ours. If that be the reason, one may naturally ask what secrets of culture have the Dutch to produce this mildness that are not open to English growers to utilise? Most probably their roots are grown in deeply-worked and highly-enriched soil and rapidly. No doubt they use water liberally, probably also sewage, so that the roots are forced into growth speedily, and being softer in texture, are also milder. Surely we have soils and situations which will afford similar conditions of culture.—A. D.

**Large Vegetable Marrows.**—I think the offering of prizes for huge old Vegetable Marrows at *Chrysanthemum* shows should be discouraged. There are other vegetables which may with advantage be encouraged—for instance, *Celeriac*, an improved type of Artichoke, little-known Scotch Kales, salads, Chicory, or other vegetables that are useful, though less showy. Recently at one of the shows in what one would consider an advanced suburban district I noticed prizes given for three Marrows, the heaviest being favoured, though quite useless as a vegetable. I admit they are used at times in a dried state, but few persons would advise their culture for this purpose, and the giving of prizes to such I think a mistake. Vegetable Marrows should be cooked in a very young state, before the seeds develop, and served whole. There is no culture in monstrosities of this kind.—G. W. S.

**Large Carrots.**—I quite agree in the main with the sensible remarks of "A. D." and "G. W." (pp. 376 and 377). One of the greatest merits of James's or the Intermediate Carrots in their best state is the small percentage of heart or core. The latter is mostly hard and strong, and unfortunately it imparts a good deal of its quality to all the flesh of the Carrot. To have this vegetable perfect, such handy sized Carrots as the Scarlet Champion should be washed clean and cooked whole. Some, however, do their best, perhaps, with their big Intermediate Carrots by halving or quartering them before cooking and cutting out all the core or heart for horses. The best edible flesh can then be cooked in less time and will be almost as mild and sweet as that of smaller Carrots cooked whole. There are two or three simple means of keeping down size and coarseness in Carrots; one is by choosing a good strain. Few now-a-days would think of sowing the Orange-yellow or Red Altringham for table use. Then the soil should be sandy, poor, deep, and no manure applied directly to the crop. Sow in lines from 9 inches to a foot or 15 inches at the most and thin to the same distance. Finally, do not sow main crops till the last of April or the middle of May. I have often noted the fact that "A. D." refers to—viz., the wonderful advance in flavour in stump or Horn Carrots in the early

spring and late autumn or winter over the average crops in similar soils and sites. To preserve the flavour of good Carrots throughout the winter I have never found any mode of storing equal the close wringing rather than cutting off the tops and storing them in small heaps or ridges in the ground without any covering of tops, litter, or straw between the roots and the earth. But when all is said and done, few vegetables need more skilful cooking than the Carrot. The finest Carrots I have eaten for many a day were in London the other day. They had hardly any perceptible yellowish core, and the flesh was red, mild, sweet and tender throughout—a good strain of Intermediate perfectly cooked.—D. T. F.

**Endive as a vegetable.**—Though rarely grown for this purpose, it is excellent in every way and an agreeable addition to the list of autumn vegetables. In my estimation it is far ahead of Spinach, and if well cooked few would refuse to partake of it. Of course, if grown for cooking, size is required, and this season the Endives of most kinds are very fine indeed, especially the Round-leaved Batavian, one plant of this grand Endive being equal to two or three of the ordinary kinds. The above-named variety is one of the best for cooking, and for that purpose needs no blanching. When well grown, with a full, compact heart, it is blanched to a certain extent, and this portion when cooked is delicious. Many persons object to Endive as a salad, but when cooked it loses much of its bitter taste. The soil being so warm late this season, the Endives made a splendid growth when the rain came.—G. WYTHES.

**Potato Renown.**—In answer to the inquiry of "A. D." (page 376), the Potato named Renown referred to by me in a recent issue was sent out by Messrs. Webb, of Stourbridge. I was not aware of the existence of another round Potato under that name until "A. D.'s" note appeared. I quite agree with "A. D." that as a rule the round varieties retain their true shape and character far better than the kidney and even the pebble-shaped sorts. I grow several of the pebble shaped Potatoes, but have a great difficulty in preserving a true shaped steak of them. On light warm soils they seem to run out to a greater length. Two years ago I saw a dish of that grand Potato Sutton's Seedling, which is catalogued as a round, disqualified, the judges maintaining that it was a kidney, and no doubt the exhibitor had selected the roundest tubers he could find. This section seems to retain the original shape better when grown on a somewhat strong cool soil. I have never known a pebble-shaped Potato keep its true form so well as the old Porter's Excelesior, but unfortunately it is rather prone to disease.—J. C.

### BRUSSELS SPROUTS.

This appears to be one of those vegetables which may be classed as unreliable, and I have some grounds for stating that there is not another vegetable which has bothered gardeners to such an extent. Of late years this has been especially so, as taking one season with another complaints generally appear in the gardening press as to its unsatisfactory state in one form or another. Either the varieties have been at fault or the season or soil has not been right. A few years ago there was evidently some truth in the assertion that the true old form of Brussels Sprout was being lost to cultivation, seedsmen, or those responsible for the keeping up of stocks, favouring the production of a large class of Sprout, handsome to look at, no doubt, but with about the rankest flavour it was possible to get in a green vegetable. When such as these were sent to the table there were found to be complaints, and no wonder, for instead of having that delicate marrow flavour, which a good Brussels Sprout should have, they were quite uneatable. Happily this is now changed as far as variety is concerned, as there are now really some capital strains. I can quite bear out what Mr. Wythes says (p. 415) as to Veitch's Paragon. It is, undoubt-

edly a capital kind, the flavour being really first-class, and if it is kept to its present characters, none need wish for a better. My plants of Paris Market are very good, the growth being very regular. At one time the plants appeared too small to suit me, but they came up surprisingly. I quite agree with Mr. Wythes as to the class of soils. There is quite as much mistake in having the soil too poor as there is in planting in too rich and loose soils. Grown on poor soils the growth is too slow to develop good flavoured Sprouts; these latter may be hard certainly, but too hard and yellow hearted to secure high quality. My impression is that it is not so much over-richness of soil that prevents the plants from forming well-shaped Sprouts, as lack of exposure. Three feet between the plants is none too much, and for such a dwarf variety as Paris Market, 2 feet in the rows and 3 feet between is enough. The plants as a rule are far too crowded. Planted closely, the plants run up certainly, but owing to the want of direct side-light, the foliage turns yellow, whilst with free exposure this remains intact almost to the last, and so assists in developing and also protecting the Sprouts. A. YOUNG.

**Quality of cooked Potatoes.**—I can confirm "A. D.'s" note on this subject (p. 377). I

Wilton House, east front. Engraved for THE GARDEN from a photograph by Mr. S. Griffin, Lucerne, Wilton Road, Salisbury.

have never found this most disagreeable feature half so pronounced as this season. Perhaps the most provoking variety is the Magnum Bonum. One end we may find a knob rather than a ball of flour, while the opposite extremity is a globe of water with blends of both in every conceivable mixture of insipidity or nauseousness between the two ends of the same Potato. No doubt the August rains after the long spell of summer drought were the active cause of spoiling so many kidney Potatoes this year. The rain stimulated the most excitable part into second growth, leaving the ripest end in a semi-dormant condition and flooding the centre of the tuber with an excess of watery sap. But all kidney Potatoes have by no means suffered deterioration to the same extent, Clarke's Main-crop, for example, suffering less from the disturbing August rains than Magnum Bonum or Champion. So far, however, I agree with "A. D." that round Potatoes have suffered least, perhaps the White Puritan least of all. But this has not always been so. Had the rain lasted long enough to environ and drown the rounds, and had they been no riper than the kidneys, possibly the whole tuber would have been waterlogged and spoiled. But we are thankful that the very early and very late Potatoes have proved

of normal quality, and that even among midseason crops some have been able to resist better than others the disorganising force and the erratic distribution of the season's rainfall.—D. T. F.

#### FORCING POTATOES.

In gardens of any size forced vegetables are in demand, and those who can supply good quality are to be congratulated, as the forcing when well done entails much trouble and a certain amount of preparation. I am aware many persons object to forced vegetables, but much depends upon the forcing and the way the roots or other green crops are finished. With time allowed for the crop to mature there would be less need to complain of the quality of forced fruits or vegetables. There are few complaints as to the quality of hard-forced fruit if it is perfect when matured. Many complain that forced fruits and vegetables lack flavour, but much depends upon the forcing, and in the case of Potatoes—those given ample time from start to finish—the quality is equal to that of roots from the open: in fact, superior, as those who force may limit the supplies of moisture at the finish to ripen the tubers, and thus obtain a

the tuber, standing the boxes in frames close to the light, in a temperature of 60°, and planting the first week in the new year. In this way very strong sprouts will be formed and there will be no blank spaces in the frames, each set will start evenly, and much time is gained by early sprouting. In frames it is not advisable to crowd, much of the vigour is destroyed; neither is it wise to use strong heat at any time, as slow forcing means few small tubers, the reverse when the temperature is not regular. The temperature should never be higher than 60° to 65° by fire-heat, with plenty of air, but not cold draughts in mild weather. The aim of the forcer should be to get dwarf haulm, and strong erect tops till the growth is nearly complete. In forcing one is obliged to use lighter soil than is often recommended for culture in the open, and this light material soon dries the tubers. Whilst swelling, the tubers should never lack moisture, the want of the latter arrests growth, and once a check is given it is not recovered. As regards bottom-heat, much depends upon the means at the cultivator's command; if by fire-heat, it is easily kept at the right temperature—70° to 80°—at the start, and I do not advise exceeding that during growth; if obtained from manure, I advise a liberal quantity of fresh leaves to be mixed; this retains warmth much longer and is not so violent as pure manure, which does not retain the warmth any length of time. In planting, the soil should be made firm, and at least 9 inches to 12 inches of soil given, adding more if the variety is a strong grower when the haulm is 6 inches high. I prefer to make the beds now and give the quantity of soil allowed a few days later, as the weight of soil causes the bed to sink, get more solid, and the bed is warmed and in nice condition to receive the sets at the date named. In soiling it is advisable to use new soil or that not much impoverished. I use old Melon and Cucumber beds, as these plants do not rob the soil much. Wet soil should be avoided, as the steam from the new bed will make it moist enough at the start.

#### POT CULTURE.

is simple; a few words will describe it. The same remarks apply with regard to preparation of seed, early planting to get good returns, and slow forcing. The advantage of pot culture is that time is saved, and earlier supplies can be secured than from frames, so that if a few dishes are wanted for a certain date pot culture will produce them in a shorter time than frames. If the sets are prepared as advised the sprouts may be 2 inches or more long early in the year. The sets should be planted in good-sized pots, three parts filled with the soil advised; failing this, use good loam, with a fourth part of old Mushroom or spent manure. The pots may vary in size, according to convenience to force. If on shelves, 8 inches to 10 inches is a useful size, with a couple of sets in a pot, but if larger, from 12 inches to 16 inches, three or five may be planted. The larger pots can often be placed in early Peach houses started in November, and near the pipes at first. Very little drainage is required with light soil, and the plants should get more soil when a few inches above the rim of the pots. If the sets are sprouted previous to planting, the weakest should be rubbed off, only leaving the strongest, and at the start very little moisture will be required, giving liquid manure when the pots are full of roots. Such kinds as Sharpe's Victor, Sutton's A1, and a good variety of Early Ashleaf (I prefer the two first for early forcing) are best for pot or frame culture, and the kinds named may be had good for Easter, that is,

drier Potato with good flavour. For years I have studied flavour in vegetables, and with great fluctuations of heat or moisture flavour is impossible. To force well, ample time must be given from the start, and for the best results in a given time it is well to grow kinds noted for earliness, and in this case flavour is a secondary consideration.

Potatoes are forced in various ways; the plan most favoured is in frames, but excellent produce can be obtained in other ways. Pots are often used to advantage, and I will briefly note the above methods and one I largely adopted with much success and at little cost when glass was out of reach. I will take

#### FRAME CULTURE

first, and the necessity of preparing the seed at this season if early produce is required. The sets are much better if prepared, and for produce at Easter no time should be lost early in December in getting well-ripened seed, not small. I prefer tubers above medium size, placing the sets thin end downwards in shallow boxes with half an inch of old leaf or other rich soil under

allowing three months from time of planting after being prepared.

I have not named ordinary culture in frames or houses without bottom heat, as it is so simple and but few can devote special pits or houses to early Potatoes. I will now note a less costly means of production, but none the less valuable on that account. Though the produce is later, it is obtained at a season forced Potatoes are much valued, and is specially suitable in country districts where glass is scarce. My plan for a good supply of tubers at the end of April or early in May is to collect all the fresh leaves available, place in bulk, turn over a few times, and in January make a large bed 4 feet thick after well ramming or treading, using enough stable litter all round the sides to make the bed neat and prevent leaves blowing about. The size of bed should be according to space and material at command; if large, four rows of sets are planted and a row missed, this allows of covering. The bed is ready to plant early in February if soiled when made, and the seed may be slightly started in frames. I cover after planting with thatched hurdles made to cover four to six rows, according to size. These are supported by 10-inch inverted flower pots, and are readily removed in bright weather. Litter or dry Bracken may be used if hurdles are not available, but covering is a more tedious process. It is surprising what a long time leaves will retain warmth, and the tubers swell and are of excellent quality by the time named. For this work I prefer the Ashleaf; it is always good, and the flavour excellent. After the Potatoes are cleared the beds are used for Vegetable Marrows, or any other purpose, and the old decayed heating material is of great assistance in the autumn for potting and other purposes. G. WYTHES.

#### EARLY PEAS.

THOSE who saw the splendid exhibit of these at the last Temple Show, from Messrs. Sutton and Sons, will have some idea of what can be grown by skilful cultivation, provided there are suitable structures at command to grow them in. As the time has now arrived for sowing, it may be well to remind those who have the command of cool Peach houses, late vineries and such-like places, that these can be utilised for this purpose. I am well aware that these structures are often required for many other things, but where room in them can be afforded, a crop of such early Peas as those exhibited on the above-mentioned occasion will well repay for any trouble that may be expended on them. It is easy enough to grow the hard-seeded round varieties, to have them ready for use at the end of May; it is, however, no light task to have the leading Marrow kinds ready by that date, especially in such a season as that experienced last spring, when on several occasions in February the thermometer fell below zero, thus in many instances necessitating fire-heat to keep out the frost. Peas, as most gardeners know, will not stand much forcing; they must, moreover, have a constant and regular supply of fresh air, without the plants being in the least subjected to cold draughts. This is not always easy to accomplish in late fruit houses, as the temperature of the-o is required to be kept as low as possible; but where there is a succession of such houses, that difficulty might be overcome. It will, however, not do to remove Peas from houses in which a little warmth has been kept to those thrown open to all weathers, as this would soon bring on mildew and ruin. Seed sown now in a cool Peach house, say in 5-inch pots, in a tolerably rich soil, should produce sturdy plants for planting out at the end of March, early in April, or for growing on under glass. One thing to be guarded against is sowing too thickly; better have half a dozen sturdy plants in a pot than a score of sickly ones, and for this reason none but the best

seed ought to be sown. It is far better to pick out all the small undeveloped Peas before sowing, and to put fewer in a pot than to sow a lot of poor ill-ripened ones, that only produce sickly plants which choke the others. If soil be used that has lain for some time in the potting shed, this will still contain a considerable amount of warmth, as its temperature will not have been reduced by the late heavy rains, which in this district have been rather excessive of late, there having fallen during the last month about 6 inches. It will not be necessary to put any crocks in the pots for drainage, as the supply of water can easily be regulated. If the pots are three parts filled with soil that has previously been passed through a half-inch sieve, the seed can then be placed on the surface. From ten to a dozen will be ample for each pot, a row being placed near the outside at a regular distance from each other, the others towards the centre. The pots can then be filled with soil, giving a gentle watering through a fine rose, with water 10° or 15° warmer than the atmosphere, so as not to lower the heat of the mould used. After this all that is necessary is to stand them as closely together as possible in a cool house till the seed has germinated, which it soon will do if the weather is mild. When the young plants appear through the soil, air must be admitted on all favourable occasions to keep the plants as sturdy as possible, but in no case should they be subjected to cold draughts. The pots should be stood at a sufficient distance from the glass to prevent the soil being frozen, should there be a sudden change in the weather. Last February, though the frost was so severe, about a thousand pots stood in a cold Peach house here without the least fire-heat, the only protection afforded being mats thrown over them on sharp nights, and, with the exception of two or three days during the early part of the month, there was sufficient warmth in the house to cause a steady growth.

Varieties of Early Marrow Peas are now getting numerous. The following is a list of those I grew last season, and with the exception of the three first, which were planted out at the end of March and grew to the height of about 6 feet, are all dwarf. The sorts were Gradus, Exonian, Duke of York, Chelsea Gem, Sutton's Seedling, Sutton's Favourite, Daisy, Sutton's Early Marrow, English Wonder and May Queen. Such a list, however, is too long, and those who are compelled to grow them on narrow borders would do well to confine themselves to such as Chelsea Gem, Sutton's Seedling or other reliable dwarf kinds, as they occupy less room and may be planted at the foot of a south wall in frames or other temporary contrivances. In all cases I prefer putting sticks to them, as the pods, being more exposed to the light, fill better. Many who are not so fortunate as to have cool houses to protect early vegetables will no doubt be desirous of growing early Peas, and such may do so with temporary frames made with floor boards and large squares of glass, both are now so cheap that for a very trifling cost long rows of seeds may be covered, but I would warn those about to sow Peas in the open not to sow the Marrow kinds thus early unless some such contrivance is used, as they will run the risk of losing them should the winter be severe. I have sown the early Marrow kinds on a warm border as early as December 8 with good results, but the seed has been protected in severe weather, and this often entails a large amount of labour not at all times readily at command. While writing about Peas, I may here mention that as Sweet Peas are often grown in the kitchen garden to supply cut flowers, these may be treated in like manner as recommended for the cooking varieties, being quite as hardy as most of the others. H. C. P.

**Tomatoes for early spring.**—I do not think there is any season of the year in which early Tomatoes are more appreciated either as a vegetable or for salad than during March and April. To the March supplies my note is not applicable, as the winter plants will be in bearing. For winter

supplies I have found it best to get strong plants from seed sown in August. I gave up the winter plants from cuttings some three years ago when we had such dense fogs, every plant having been killed, whereas the smaller plants from seed escaped. Many have not convenience to grow winter Tomatoes, but there is a great gain in growing a few plants for early spring fruiting. To do this, seed should be sown in October and the plants grown near the light on shelves in a temperature of 60°. If wintered in 4½ inch pots, the plants will be fit to pot up into 8 inch or 10-inch pots early in the year. Treated thus they will show blooms in January, and will give nice crops in April at a season Tomatoes are valuable. The chief points in culture with the winter plants are plenty of light, just enough moisture to keep them going, and no manure of any kind till the plants are in their fruiting pots. Many give too much warmth and a thin, weak growth results. At the same time a coarse growth is not required and should not be encouraged. It is not advisable to let the plants get pot-bound. Even in the winter season a small shift may always be given if the plants are kept close to the glass and carefully watered. At the final potting bone-meal is excellent as it does not build up a strong growth, but a short-jointed, fruitful one. Firm potting is also necessary.—G. WYTHES.

#### POTATO DETERIORATION.

I HAVE never held to the theory that Potatoes have deteriorated or have in any way become more subject to the attacks of the disease through such assumed deterioration. It seems odd that any authority on Potatoes should put forward such a suggestion in face of the fact that, more than in any other way our Potato crops have been saved from almost decimation through the agency of such robust varieties as are those which are classed as disease resisters. Again, it is perhaps not generally known that even natural species which have never been subject to intercrossing, and are to-day in exactly the same unimproved condition as they were in Raleigh's time, are just as liable to be affected by disease when grown outdoors, as are the ordinary varieties in use. So far from Potatoes having deteriorated, they are as strong in growth, many, indeed, far stronger than they were fifty years ago, when the disease first made its appearance. When Potato plants produce pollen abundantly, and just a few do so still, as is evidenced by the fact that they set their blooms freely and produce seed Apples largely, they are never great croppers. On the other hand, those which produce no pollen are generally good croppers, the bulk being very heavy ones.

During the past summer I grew seventy varieties of Potatoes in diverse parts of Surrey, and seed-apples were rare indeed, although the hot, dry summer was just the sort of weather to promote fertilisation. The chief varieties of potatoes I have met with during the past twenty years as pollen producers so freely as to set their own flowers in considerable abundance, were one American variety named American Purple, the pink-eyed Radstock Beauty, the red Reading Russet, and the white Woodstock Kidney. The last was, because a handsome variety, of excellent quality and free with pollen, very largely used as a pollen parent, and has been the progenitor of thousands of seedlings. It must be noted, however, that perhaps not one seedling in a thousand would repeat that free pollen-bearing characteristic, and all these varieties have all along been just as susceptible to disease as any others. Whatever deterioration has come to Potatoes, is not from intercrossing but rather from bad storing of seed. I have proved that to be the case in myriads of

instances where weak growth and indifferent cropping are due invariably to the wet upon planting tubers, thus causing heating, premature sprouting and waste. Seed tubers kept fully exposed to light and air, never heated or prematurely sprouted, and planted in full possession of their habitual vigour, always manifest ordinary robustness and give heavy crops. Then it is assumed that varieties wear out in time. That is all pure assumption. The Ashleaf Kidney, never a strong grower, is as good to-day as it was 50 years ago. It is all a case of yearly selection and good storing. Because this variety is an early one and rarely saved in bulk, the tubers for seed get better treatment. They are usually set out thinly in cool sheds on shelves or in boxes, and are never sprouted to their injury. Hence it is that this old variety contradicts in itself that incorrect assumption that naturally varieties of Potatoes will die out. Where carefully grown and preserved even the ancient Fortyfold is as good to-day as ever it was. Then again there is the assumption that Potatoes deteriorate if the same variety or rather same stock be grown on the same ground for many seasons in succession. That, too, is a fallacy when seed tubers are properly cared for. On stiff clay soil in Middlesex I grew stocks for many years in succession without finding the least deterioration. It may be true that a change of soil does influence the growth and cropping of varieties the first year, but I never found that effect to extend to a couple of years. Again, that effect is not always found, but it is occasionally so, and some observers have in consequence jumped too hastily to conclusions. From a trade point of view it is a capital theory to propagate, and I do not blame traders for working upon it. I am, however, discussing this question from a purely physical aspect, and in that sense adhere fully to what is written. So long as we treat the Potato tuber naturally, there is little danger that it will become weaker in constitution.

No doubt the best store for seed tubers in the winter would be in the soil, could we safely leave them there. That, however, will not do, and if we may not so store them, then the next best thing is to give them artificially the nearest of natural conditions. Place them in thin layers so that no warmth is generated, with plenty of light and air to harden the skins, and when eyes push, as of necessity they will push in time, under any condition of storing, the abundance of light and air will keep the young shoots stout and healthy, so that when the tubers are planted, these shoots are of that stout robust nature they would have been had the tubers been left in the ground all the winter, and had escaped frosts and other enemies.

A. D.

**Preparing soil for winter cropping.**—It is always a great advantage to the gardener if he can have his kitchen garden soil prepared for spring cropping by deep digging or trenching in the winter. Yet it is a fact that this sort of work often needs for its performance or otherwise the guidance of the future, and that future cannot be seen into. There can be no worse results to stiff pasty soils, just those of all others that need aerating and pulverising through the agency of frost and wind, than when we get a succession of wet weather following upon the roughing up of the ground. Then does it become saturated, the pores of the soil are closed as with paste, water is retained, and when dried it resembles baked clay. That is a most unhappy state of things. Could the nature of the weather during the winter be foreseen, then the working of or letting it alone could be determined. In the case of light, porous or sandy soils, such as under all ordinary conditions admit air freely, little of roughing up is needed, although they always are the better for

deep working. But trenching cannot be left till the spring, and therefore must be done in the winter, so that everything as to the nature of weather following has to be chanced. There can be no question, however, let the nature of the soil be what it may, that aeration goes on even more thoroughly in the winter when carrying a green crop of some description which may in the spring be dug in and thus form excellent manure. There is no better crop for this purpose than Tares. In many cases it would be far better to have otherwise bare pieces of soil sown with Tares thickly, and perhaps a little Rye also, at the end of September. Growth soon ensues and there is in March quite a dense coating of green matter to dig in, whilst the soil is more open and porous than if left uncropped.—A. D.

**Early decay of Celery.**—There are complaints in this neighbourhood, and which is also my experience this season, of the decay of much of the earliest Celery. I attribute it to the extreme heat experienced, and which was followed by heavy rains, the result being that the soil in the ridges became almost like a mild hotbed, causing rapid blanching, followed quickly by fermentation and consequently decay. I do not know what else it could be, as later-earthed plants are all right. Such results teach a lesson as to not being in too great a hurry to commence earthing. A portion of the earliest must be done to secure an early supply, but a part should be earthed up later.—A. YOUNG.

## TREES AND SHRUBS.

### THE RED DOGWOODS.

Few plants introduced into England are more effective than the common Dogwood, of which the usual name is *Cornus alba*. It is a shrub which, like many others, has allied kinds that are somewhat like it, and there is some confusion in consequence. The differences that may occur among such things may be made clearer by the following notes on these species by Mr. George Nicholson, of Kew.

#### DOGWOODS WITH RED BARK.

**CORNUS BAILEYI.**—Along Great Lakes to Canada. Habit erect, not stoloniferous. Height 6 feet to 8 feet. Bark reddish brown. Fruit pearly white. Figured in *Garden and Forest*, 1890, p. 465, f. 58.

**C. STOLONIFERA.**—Red osier Dogwood. N. America. Height 3 feet to 9 feet. Bark bright red-purple. Fruit white or lead colour. Sends up many suckers, and makes a good cover plant for game, liking damp spots.

**C. ANOMUM (OR C. SERICEA).**—Kinnikinnik. N. America. Branches purplish. Fruit pale blue. Height 3 feet to 9 feet.

**C. ALBA.**—North Asia. Fruit white, shoots intense red. This is the species most commonly cultivated. The variety *sibirica* has even more brightly coloured bark, but it is not so free a grower as the type. Leaves go off in some seasons into good yellows and reds, but the winter effect is most gorgeous.

**C. SANGUINEA.**—Our native Dogwood, not to be despised as an ornamental shrub, the decaying leaves deep red; fruit black, branchlets red, but not clean and bright like those of Nos. 1, 2, and 4.

Having cleared the ground as regards the kinds, it may be well to say, in regard to general effect, that all that is desired in this way may be obtained from one or two kinds. But as important differences as regards effect very often arise in varieties of the same plant (as in the case of the beautiful red and yellow-twigged varieties of the common Willow), so closely allied species of Dogwood give us different effects. As regards the soil for these plants, they are happy almost in any, and never more effective than when massed about lakes and

ponds in wet soil, although in our country they will grow in almost any. As covert, it is often important to have things here and there that do not grow beyond a certain height, say that of a man, and these Dogwoods are among the best things we can count upon for this purpose. We find the variety *sibirica* brilliantly effective, and one of the best things we have ever planted was a large group of these, associated with the red-twigged Willow (the tall cardinal Willow). Both are beautiful in autumn leaf, and even prettier in winter, owing to the fine colour of the red Willow when bare harmonising so well with the twigs of the Dogwood.—*Fidd.*

**Bambusa Veitchi.**—At a little distance this will just now at once attract attention, for the leaves appear to be regularly and freely margined with white; but closer inspection reveals the fact that the variegated appearance is caused by the edges of the leaves being quite withered. The leaves of this are each over 2 inches in width, and about 6 inches or 7 inches long. It is a free-growing plant and soon forms a dense mass or clump. This Bamboo reaches a height of about 2 feet, so it must be considered as one of the dwarfs of the genus. A near relative is the larger and bolder-growing *B. palmata*, which is such a handsome, fine-foliated plant that a place should be found for it in most gardens if possible; this reaches a height of 5 feet to 6 feet. Neither of the two kinds here mentioned should be associated with delicate subjects, as the rhizomes are very aggressive and would soon injure any less vigorous plants.—T.

**Autumn tints.**—The short duration of these on the Oaks, clothing miles of steep hillsides visible from here, was remarkable this season, for owing, I suppose, to some climatic influence, the trees retained their foliage and presented nearly as green an appearance as at midsummer—with nothing but an occasional fiery Beech and golden Birch to relieve the monotony—up to November 1. In three days, however, the whole was changed and the whole district one mass of colour. Never before have I seen such a mass of colouring on the Oaks. We were deprived of the glorious picture as suddenly as it appeared, for in the following week extremely heavy storms of wind and rain quickly spoilt the whole, and now we have yet another change of scene, prominent being the high, snow-capped surrounding mountains, with, far and near, snug greystone built, slate-roofed villages, farmsteads and solitary cottages blending harmoniously with their surroundings—not your garish-red brick and tile erections. The swollen mountain torrents tumbling madly down to the placid and tortuous river in the valley below; the grey, bold rocks, the various coloured boles of forest trees, the glaucous and glistening evergreens, and the infinite network of Fern and lichen-covered branches down to the bright shoots of Dogwood, golden wands of Willow and the *Pernettyas* in berry at the water's edge, all combine to produce a unique wintry beauty.—JNO. ROBERTS, *The Gardens, Tan-y-birch.*

**Philadelphus Lemoinei.**—The planting season must be my excuse for a few words in favour of this very desirable member of the Mock Orange family, and which this year has been much admired. At Kew during the summer it attracted a large share of attention, and in the last vol. of THE GARDEN Mr. Goldring speaks of it as "the most glorious new small shrub I have seen for years." This *Philadelphus* is one of the many valuable plants that we owe to M. Lemoine, of Nancy, who obtained it by the intercrossing of the little new Mexican *P. microphyllus* with the European Mock Orange (*P. coronarius*). When *P. microphyllus* was first introduced (in 1883) doubts were expressed as to its hardiness, but it proved to be all that could be desired in this respect. M. Lemoine was not long in utilising the new-comer, for he distributed the hybrid form *Lemoinei* in the autumn of 1887, since which time he has sent out other varieties, but none of

them surpass Lemoinei. This last is in general appearance about midway between its parents, forming as it does a free-growing, twiggy bush, whose shoots, and especially the vigorous ones, all have an upright tendency. These shoots are about the middle of June completely wreathed with white flowers, which are borne in such quantity as to form quite a white mass. Other very desirable features are that it lasts a long time in bloom, and it has proved perfectly hardy even during the rigours of last winter. When *P. microphyllus* first flowered after its introduction one feature that caused it to be particularly noticed was the fragrance of its blossoms, which greatly resembled that of Pine apples. This fragrance was transmitted to the progeny, and so pronounced is it, that a bed or clump of the variety Lemoinei can be detected for a considerable distance. This Philadelphia can be planted in various ways, and one of the most effective pictures I have seen was a large circular bed, the central portion of which was planted with a number of *P. Lemoinei* and edged with the smaller *P. microphyllus*. As this latter is a little later in flowering than the other, the beauty is retained somewhat longer than would be the case if *P. Lemoinei* alone was used. Another of M. Lemoinei's hybrid varieties of Philadelphia received a first-class certificate from the Royal Horticultural Society last June. This was *Boule d'Argent*, said to have been raised from *P. Lemoinei* crossed with the double form of *P. coronarius*. In *Boule d'Argent* the flowers are semi-double, while the plant appears to be in habit a good deal after *P. Lemoinei*.—T.

#### PLANTING SHRUBS.

It sometimes happens when entering on a new place that a gardener finds a number of choice evergreen shrubs (known commonly as American plants) scattered here and there about flower garden and shrubbery that have been planted without due regard as to whether soil and subsoil are in any way suitable for them, with the result that in the majority of cases they are in very indifferent health. Where this state of things exists this is a good time to see about their removal, with the view of giving them in the first place a more congenial compost and restoring them to health. It may be noted that where this is necessary it is not advisable to dot the plants about as single specimens, but rather to group them together in some large beds where effectual provision can be made for their reception. Where the natural soil is not suitable it must be excavated as deeply as the plants are likely to penetrate (they do not root deeply), and if a supply of peat is not available, a fairly good substitute may be found in a compost consisting of two parts turfy loam, one of leaf soil that is free from sticks and the fungoid growth that is associated with decaying wood, and one of dry cow manure, each ingredient being thoroughly chopped to pieces and the whole well mixed together. Any plants that are in indifferent health should, when lifted, undergo an examination of the roots, and anything here that is dead or partially decayed should be cut clean away; also, if the condition of the roots is not satisfactory and the plants are on the dry side, it is advisable to soak the balls before planting rather than giving a lot of water after planting; in fact, cultural operations in this direction would be identical with those found essential in the case of hard-wooded greenhouse plants. A good thick mulching of half-decayed leaves may be put on the beds after the planting is finished, and if at the end of the first season in their new quarters the plants have benefited by the change and are doing well, the mulching to be afterwards annually applied may consist of cow manure. With these evergreen shrubs may be associated groups of deciduous Azaleas—their flowers will show to advantage against the deep shiny green foliage of *Kalmias* and the choicer *Rhododendrons*; whilst, if an edging is considered necessary, this may consist of a broad band of hardy Heaths. If a summer display is required in such beds, the spaces between the shrubs may be planted with

Lilies and Gladioli in variety, also *Galtonia candicans*. Any such planting should, however, be done thoroughly; an occasional flower popping up here and there is not satisfactory and has a patchy appearance. If the propagation of the choicer deciduous-flowering shrubs by layering was carried out last season as previously advised, the layers, if not already lifted, will now be nice plants, and may be carefully removed. They will be acceptable for grouping in any bare spots in shrubberies, or, if time permits, common overgreens can be taken away to make room for them. It is advisable if possible to group together a fair number of each variety or species; a better and more imposing idea of their beauty is thereby obtained. E. BURRELL.

## FERNS.

### ADIANTUM FARLEYENSE.

ALTHOUGH there is little difficulty in growing on healthy young plants, it is difficult to get old plants, or those which have got into a bad condition, back into a healthy state again. To have healthy, vigorous plants, young stock must be grown on from time to time. As this Fern never matures spores, it is necessary to propagate by division. The best time for doing this is early in the spring, when the plants are growing freely. I find when old plants are divided they are very slow to become re-established, but if young plants which have not got pot-bound are divided into, say, three or four and carefully handled, they will start away without losing a frond. They should be potted in rough porous compost—good fibrous loam, leaf mould and plenty of sand. Plenty of drainage should be used, the plants being potted moderately firm. When divided they will require to be kept close and shaded for a few days, and care must be taken not to give too much water. After the plants have taken root into the new soil they should be gradually exposed. In the after-treatment the main point is careful attention to watering. In many instances over-watering is the cause of failure, while there is nothing more damaging than to allow the soil to get too dry. After the pots are well filled with roots the plants will take a deal of water; in fact, there are few Ferns which take up more water than healthy plants of *Farleyense*. A regular temperature—which should not fall below 60° or rise above 70°, unless by natural summer heat—is better than giving too much artificial heat. A light shading is necessary during the summer, but plants should never stand under the shade of others or be crowded up. If stood up on inverted pots or suspended to the roof, they will thrive well and the fronds will be of better substance than under heavy shading and moisture, besides which, the young fronds will have that lovely pink tint which is so much admired in Ferns. I have grown *A. Farleyense* among other plants where it has been necessary to use the syringe freely, and have not found it suffer thereby. The chief causes of failure are over-potting, heavy shading and over-watering. II.

### HARDY FERNS IN WINTER.

OUR British Ferns when growing in their natural habitats find ample protection during the winter from the leaves and grasses which gather round them, and their own ripened fronds also afford further protection; besides which, they are mostly found in very sheltered places. This is not always taken into account by those who cultivate the British Ferns, and when we get a severe winter like the last a great number are entirely destroyed and others so much crippled, that it takes a whole season for them to recover, and even then they do not make such nice plants as those which have had sufficient protection to keep the crowns in good condition. One great cause of hardy Ferns suffering more when under cultivation than when growing naturally is that they make their growth, or rather continue to

grow later in the autumn, and are not so well ripened. They also are much more liable to suffer when grown in pots, more especially if the pots are not plunged into the ground. I do not recommend giving any artificial heat to keep off frost, but all grown in pots should be plunged. In a pit with a northern aspect is the best position, but, failing this, anywhere in the open ground will answer nearly as well. All the deciduous kinds may be covered up on the appearance of the first frost. A good covering consists of a few pea sticks or other brushwood being laid over first, and then a good covering of Bracken for preference, and if this is not at hand, straw may be used. The *Scelopendriums*, *Polystichums*, and other evergreen sorts should be uncovered during mild weather. I may here mention that *Scelopendriums*, though among the hardiest, suffer much from frost if they have been making fronds late in the autumn. Young plants also require protection. If they can be kept in a pit with lights over them, they must be opened as soon as the temperature rises above freezing point. Those which have ripened off early in the autumn will make a fresh start if given the slightest encouragement, and will then suffer as soon as we get a return of frost. Even when growing wild I have seen many instances where they have started early in the spring, and then have been cut down by a late frost. This has been particularly the case with the *Athyriums*. Although every care should be taken to prevent hardy Ferns starting prematurely, after they start naturally in the spring, a little warmth will be beneficial rather than otherwise. We now have some very beautiful varieties of the Lady Fern (*Athyrium Filix-femina*) which make splendid subjects for pot culture, and when started early in the spring in a cool house where the temperature can be kept just above freezing point, such varieties as *plumosum dissectum*, *superbum*, *pulcherrimum*, *Kalothrix*, &c., are among the most beautiful subjects that can be found. It will not do any harm to start hardy Ferns early in the spring provided they can be protected in case of frost. Those ripened off early in the autumn will start away freely without much encouragement.

If a little more attention were paid to the natural requirements of our British Ferns, I think they would become greater favourites than they are at present. A. HEMSLEY.

## GARDEN FLORA.

### PLATE 1044.

#### ROSE G. NABONNAND.

(WITH A COLOURED PLATE.\*)

NEW Roses are forthcoming as regularly as the season for planting rolls round, and nearly every year sees some particular variety permanently added to its class. The number of selected ones is very disproportionate to the rejected of the same year, but this is inevitable, as we judge the new ones from a high standard of merit. In 1889 two first-rate Tea Roses, quite opposite in character, but equally deserving of popular favour, appeared. To one of these, Ernest Metz, a very full measure of favour has been accorded. This Rose happens to be favoured by exhibitors, and consequently its merits have been made well known by its frequent appearance at Rose shows. On the other hand G. Nabonnand, the Rose here figured, and which also appeared in 1889, is one that exhibitors would never bring prominently forward, yet of all the Roses that the last decade has brought us there are none more pleasingly distinct or consistently beautiful. All who, disregarding past traditions of Tea Rose culture, are now endeavouring to make these

\* Drawn for THE GARDEN by H. G. Moon at Gravetye, Sussex. Lithographed and printed by Guillaume Severeyns.

lovely Roses one of the summer features of their garden by growing them in bold groups, must include *G. Nabonnand*. The plant has a good robust constitution, growing freely and fairly tall, in this respect much resembling another fine kind for grouping, namely, *Mme. Charles*. It is second to none for persistency of blooming, but of even more importance is its all-round value alike under the varying conditions of sunshine and showers that make up our variable summers. It is hardly possible to recall two successive Rose seasons marked by such extremes of favourable and unfavourable weather as those of the past two years, and it is strong testimony to the merits of this new Rose that it was first-rate in both seasons. The brilliant sunshine of the past summer and autumn, sun-dyed the flowers with glowing tints that were not present the previous year, but the form and delicious scent are apparently fixed and constant charms that every season will permit us to see and enjoy. The accompanying plate shows rich colour-harmonies that words would fail to justly describe, and although the brilliancy of the colour may vary with the time of year, flowers are sure to be abundant and fine throughout the long period of Tea Rose days.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**SOWING PEAS FOR PLANTING.**—For a good many years I followed the common practice of sowing my first early Peas in January or February in small pots, and giving them the heat of an early vinery or Peach house until an inch high, removing them afterwards to a cooler house for a fortnight, and finally to a frame. I have, however, abandoned that course, having seen the good results secured by several gardeners by sowing early in December and standing the pots in cold frames. There is not much labour attached to this; the chief thing needed is plenty of air, as the soil needs very little water until the growth shows itself. Instead of the orthodox small pots, those 4 inches in diameter are used, draining them well and using a good stiff loam, kept open by the addition of a little fine mortar-rubble, or road grit. Sow thinly, as crowded growths not only smother each other, but the roots get so entangled that much damage is done when the ball is slightly broken at planting time in March. The pots should be plunged to the rim in either ashes, leaf-mould, or cocoa fibre, and the lights covered on very cold nights. As regards varieties, I grow *Chelsea Gem* and *Stratagem*. The latter is very hardy thus treated, and comes into use about the time *Chelsea Gem* has been gathered. Another capital medium-height Pea, and one possessing a grand constitution, is *Wordsley Wonder*. It is simply astonishing how this variety will yield under good culture, the individual Peas also being much larger than most of the early white-seeded sorts. An eye should be given each morning when air is given, as a single mouse will ruin a whole batch in a few days. It is a good plan to peg down a few branches of *Furze* round the sides and ends inside the frames. This will often prevent mice from gaining an entrance.

**FRENCH BEANS IN BEDS.**—Where the pits or beds in Melon or Cucumber houses are not wanted for plants, they may now be profitably utilised by first laying a good foundation of leaves in a fresh state and placing thereon 6 inches or 8 inches of light loamy soil containing a fourth part horse manure, the same being first made firm, afterwards drawing shallow drills with the trowel a foot apart. French Beans may then be sown, no variety succeeding better under this mode of culture than *Sion House*. The bottom-heat valves, if any, must be turned nearly off so as to reduce the heat at the roots to about 70° or 75°, aiming at

a top temperature of from 60° to 65° and keeping up a moist growing atmosphere. With a moderate heat of this kind red spider is never troublesome, and the plants do best if not syringed overhead, especially when in flower. Beware of over-watering, as the stems, when in a young, soft state, are very prone to rot at the base. As these become hardened and the foliage more abundant, two waterings weekly with weak farmyard manure water will help them much, stirring the surface of the beds at intervals to admit air. A little fresh air should be given daily in fair weather, even when sun is absent, closing at 2 p.m. and keeping the evaporating pans supplied with a little weak liquid manure or guano. Where two beds exist in the same house, the second one should be sown as soon as the first lot of plants shows for bloom. When resowing, fresh soil need not be given, the same answering well if it is well stirred and a little artificial manure added. Some growers prefer to sow in pots and plunge them in the beds of leaves, and certainly this plan has much to recommend it, as plants at this season are much less liable to suffer from over-watering when the roots are confined to a narrow limit.

**FORCING LETTUCE.**—Where plenty of Lettuce in spring is imperative, it is well to sow now seed of any of the small Cabbage section, and to prick it out on a gentle hot bed at the end of January. Sow in a box and place in an intermediate house, thinning out as soon as the seedlings can be handled, and raising them close up to the roof glass to ensure a stocky growth. If *All The Year Round* or *Tom Thumb* is used, it is astonishing what a lot of good Lettuces may be cut in April from a two-light frame raised on a bed of warm leaves and manure, and surfaced with 6 inches of good garden soil. Of course with a fair winter those protected by cold frames will supply all spring wants, but as one never knows what frost is in store, it is always safe where there is a heavy demand to provide against all possible contingencies. It is almost useless sowing the *Cos* varieties at this season, as their growth is not only much slower than that of the Cabbage varieties, but weaker also.

**PREPARING FRAME POTATOES.**—It is now quite time tubers of *Sharpe's Victor*, *Mona's Pride*, or *King-leader* were placed in order in boxes, and given comfortable quarters in a greenhouse or tolerably close to the windows in a warm potting shed, in order that they may come on gradually and form Sprouts an inch long by the second or third week in January. This is a far better plan than postponing it until a week or two before they are wanted for planting, and then forcing them on unduly in warm vineries or Peach houses. I like to put a little leaf mould in the bottom of the boxes for the young roots to work into, as if lifted out with care these may be preserved whole, and a much quicker and robust after-growth ensured than when the tubers are entirely without roots. When, however, too much rooting material is placed in the boxes, basal rot often follows, or a superabundance of roots is made, making it quite impossible to separate them.

**SEAKALE THONGS.**—As each batch of *Seakale* is prepared for forcing the root-thongs should be saved and cut into lengths of about 6 inches, the top portion being made quite smooth, and all finally laid in a box or frame and covered with fine sharp soil to induce an early callus and sprouting. When sufficient has been saved in this manner for the earliest planting the rest may be laid in out of doors, the foot of a south or west wall being the best situation. Some lay them in roughly at trimming time, and cut them over later on, but this is a loss of time and brings growth much later in spring. Where the *Lily White* is grown, as many thongs as possible should be saved, as this is undoubtedly an advance on the old variety, although, in my opinion, less adapted for very early forcing.

**EARLY RADISHES.**—It is possible to obtain nice tender Radishes early in the new year by sowing now on a gentle hot bed and covering with a frame. In forming the bed the use of stable manure should be avoided, as the least excess in

bottom-heat causes a spindly growth and invariably ends in failure; use all leaves, tread firmly, and allow about 6 inches of light open soil for a rooting medium. Sow *French Breakfast* and *Wood's Frame*, thinning out very freely as soon as possible, and admitting plenty of air from the time germination takes place, as colling is ruinous, especially at this time of year. Growers about London sow in open beds at this date and cover with long litter, but constant attention is in this case necessary, the litter being removed each morning in fine weather and replaced at night.

**MINT AND TARRAGON.**—A sufficient quantity of roots of these two herbs should now be got under cover to meet the demands of spring. Mint does very well in moderately deep boxes, a fair proportion of rotten manure being mixed with the soil. Tarragon responds well to the same treatment, and by getting it in now undue forcing is avoided and the growth is sturdy. For early use a few roots of Mint may be laid on the border of an early vinery or Peach house and covered with leafy soil, keeping it moist with the syringe. Sow Mustard and Cress in small quantities and often, rather than large boxes at one time, as it quickly becomes tough and uneatable during the winter months.

**PREPARING SOILS.**—Take the earliest opportunity of laying in a sufficient bulk of soil for use in spring. It is now in a comparatively dry condition, and success in growing early Tomatoes, Cucumbers, Melons, French Beans and other spring-sown subjects very much depends on the condition of the soil in which the seeds are sown. Frost and snow may occur at any moment, and if once the compost gets into a wet and sticky condition, it is not easily remedied. A good cart-load will go a long way in sowing and planting these early crops. J. CRAWFORD.

### HARDY FRUITS.

**PLANTING OPERATIONS.**—The weather so far has been favourable for planting on light soils. I admit the last week in November was not at all good on clayey land, rain falling daily. The planting should now be pushed on rapidly, as in my opinion, fruit trees do much better when planted at this season than when this work is deferred till the year is well advanced. It may be thought advisable at this season to destroy worthless trees, and no time should be lost in selecting new ones. It is useless to allow old worn-out trees to cumber the soil; they do not add to the appearance of a well-kept garden, and in many cases harbour all kinds of insect life. Again, some of the very worst kinds, among Pears especially, form the most shapely trees, and one hesitates to remove them. We have but a limited number of really good Pears, and their season is but a short one, so that only the best should be grown. I noted the importance of careful planting in an earlier calendar, and need not repeat my remarks. I would urge the necessity of fresh soil for new trees in impoverished land, omitting manure except in the way of a final mulch on the surface after planting. Much of the work as regards preparation can be pushed on before the trees arrive. In clay land it is not well to puddle the soil, but whenever possible a fresh site should be given new trees. The latter remarks are also even more applicable to bush trees. Gooseberry bushes should never get the same position the former trees occupied. Currants get their roots covered with a white fungus in poor soils, and even old trees, both of Gooseberries and Currants, if carefully lifted well repay for new soil and replanting. Trees that arrive during frosty weather should be placed in a cellar or cool store till thawed. If kept moist at the roots they may be planted at the first favourable opportunity.

**PRUNING FRUIT TREES.**—This will be one of the most important details in this department at this season. As regards pruning it is difficult to advise as the trees require diverse methods on certain soils and stocks, and the way in which the trees are grown. I am aware in many gardens it

is impossible to allow the free growth some kinds require. There must be small bushes, and these certainly have a nicer appearance than trees of all sizes and shapes. In such a case root-pruning is a necessity. In fruit gardens one may give the various kinds the treatment required. Take the case of drooping varieties of Apple trees. To cut these hard back is a mistake, as the fruits in some instances are borne on the points of the shoots, and if severely cut there would be little return. I am a great advocate for thinning out where it can be practised, and if a certain amount of shortening back is done occasionally, the trees do not get unsightly or cease to bear. This is more advantageous than severe pruning yearly. Much can be done during the summer in the way of removing gross shoots, so that at this season but little pruning is required with small trained trees. Wall trees should not be allowed to make long ungainly spurs, as if these are allowed the trees do not get the benefit of the warmth the wall affords and but few fruits are obtained. Now is a good time to reduce the numbers and shorten back the spurs. If a certain number are cut hard back at equal distances all over the trees, doing the work in two or three seasons, the trees will be then well furnished with short fruiting spurs. In pruning, the Cherry, Pear, Apple and Plum should be gone over first, leaving the Peach and the Nectarine till the latest moment possible. Newly planted trees should not be pruned now, shorten the tops if desired just before growth commences in the spring. Cherries such as the Duke and Bigarreau section fruit mostly on spurs, and any long shoot not wanted for extension should be cut back to the second or third bud from the base. In nailing in terminal shoots avoid crowding as the trees soon get infested with black fly when crowded.

**PEACHES AND NECTARINES IN WINTER.**—Many good growers advise leaving the Apricots till early in the year before pruning. I do not. In my case there is little to prune, as by attention to summer stopping, the chief work is extension of terminals, giving more room and equalising the space between the new wood. By allowing the trees to grow freely there is less canker and gumming. The Apricot being the first to open its flowers, it is well to attend to it first. Remove poor surface-soil down to the fibrous roots and top-dress with good loam, decayed manure and bone-meal. The trees always do best when the roots are near the surface. The Peach and Nectarine flowering early, it is advisable to retard the bloom as late as possible and to harden the wood by exposure. To effect this it is a good plan to unnaal all new wood of the last season or wood with fruiting buds. By so doing the wood is hardened, the buds retarded, the shoots also get well cleansed by winter rains and are ready for pruning just as the buds begin to move. When these trees are dirty, it is well to remove as many ties or supports as possible, well cleansing with quassia and soft soap or soluble paraffin, and then giving the strong branches new ties and burning old nails before using again. It may be necessary with trees badly infested with scale to paint the old wood with insecticide, as the pests have such a strong hold at the back of the branches. Peach trees which have suffered from mildew when at rest may with advantage get a thick solution of sulphur with a small portion of fresh lime to make the sulphur adhere to the branches. This should well cover the trees and all parts of the wall, the dressing being more effectual when the young wood is free of the wall.

**BUSH FRUITS—GOOSEBERRIES.**—The pruning of these trees is often delayed as long as possible in consequence of the loss of buds by birds. The bullfinch and others will soon be on the alert and do much mischief. I do not advise delaying pruning, but take measures to keep these pests away. I am not an advocate of the severe pruning often practised. Of course it is necessary to well spur back the plants trained on walls, but the close cropping over is not advisable. I advise the thinning of shoots, shortening loose or straggling branches, cutting back to a well placed inner shoot and removing of sucker growth,

shortening any branches that press down towards the soil. It is not necessary to thin severely, only sufficiently to admit light and air and gather the fruit. I prune half the trees rather severely one year and do not prune much the next, merely taking out cross shoots and suckers. By this means I have one half with a heavy crop, those hard pruned only bearing a light one, but the fruits are larger. To preserve the buds after pruning, it is well to give the trees a thorough syringing with fresh quicklime and soot, well covering all parts of the trees. Near towns where sparrows are plentiful, the mixture may be made with quassia water. After much rain the trees will need redressing. By pruning now and manuring, forking between the rows, the quarters present a neat appearance and the trees get the benefit of the food given, rains washing the food to the roots.

**GOOSEBERRY PESTS.**—In many old gardens the caterpillar and red spider were most destructive last season. The latter is easily got rid of, as it only thrives when moisture is deficient, but unless the trees are well cleansed it is likely to reappear next season. A thorough washing with Gishurst compound, with a little sulphur added, will remove all traces of the pest. Fresh lime for scaring birds also cleanses the trees from these pests, and, in damp localities, prevents Moss growing on the older branches. For caterpillar, different measures must be taken, as the grubs are in the surface soil and in cocoon form, ready to attack the trees next summer with increased vigour. I advise the removal of old surface soil from under trees. Burn the soil removed, and replace with new, enriched with manure and bone-meal, giving a dressing of fresh lime before adding the new soil. In districts where tan is readily obtained, a good dressing of fresh tan or gas-lime broken finely and placed on the surface at this date will kill the grub.

**CURRENTS.**—The pruning of these should now be completed and the space between the trees forked over. The Red and White Currants require similar treatment. The branches require to be closely spurred in to within half an inch of the main branches. The tree should be open in the centre. Any terminal or leading shoots must be cut, according to the size of trees desired. Black Currants are not pruned like the above, but treated more like Gooseberries, that is, the shoots thinned. These fruits are often too much crowded. It is well at times to remove a small number of old branches, and train a few of the strongest new shoots to take their place. Birds also take the buds, and the dressing advised for Gooseberries should be used after pruning. It is not too late to get new trees from cuttings of bush fruits. Select strong shoots, shorten to 12 inches or 15 inches in length, remove all buds half way from the base, and then plant in drills 6 inches deep, the cuttings 6 inches to 9 inches apart; well firm the cuttings as the drill is filled in. Replant next autumn in rows 18 inches apart each way in well-manured land. G. WYTHES.

**Birch for brooms.**—It is customary in some large establishments for the garden labourers to make brooms in stormy weather, and as the material is always better for being stored for a time before being used, the present is a capital time of year to cut a sufficient quantity for one year's use. If large branches are cut and stored away in a dry, cool chamber they will gradually harden without becoming brittle. A handy labourer will make several dozen brooms in a day, and as a rule they are far more durable than those purchased from hawkers.—J. C.

**A good turf for poor soils.**—The best of all Grass-like plants for furnishing and embellishing dry positions and poor soils is *Carex alba*. In the course of last summer, when all the Grasses on our mountains were parched up and wretched looking, *Carex alba* looked luxuriant and thriving even when growing in the most unfavourable positions. So much were we impressed by it that we introduced some tufts of it into our Alpin

Jardin d'Acclimatation, where we subjected them to very severe tests in dry positions without the least detriment to the green appearance of the plants. This *Carex* is perfectly hardy, withstands not only very dry weather but also excessive moisture, thrives in the stiffest and most compact soils, and flourishes even under large trees in positions that seem least favourable to vegetable growth. *Carex alba* is of a lively green colour, and the plant is quite as effective in its appearance as Rye Grass. Under trees and in dry, shady positions, and also in very exposed, arid places it succeeds where other plants would perish.—H. CORREYON.

## ORCHIDS.

### ODONTOGLOSSUMS IN WINTER.

IT has been remarked in reference to these beautiful Orchids that they are of the easiest culture, and that they thrive well in a greenhouse, &c. Misled by these statements many persons have been induced to purchase plants whose accommodation for them is not only very limited, but eminently unsuitable. This is quite obvious from the number of queries that come to hand respecting their culture from persons who have little or no experience with them and have failed, not from want of attention on their part, but for the reasons mentioned above. I do not say that *Odontoglossums*, as a rule, are difficult of cultivation where they are properly accommodated and judiciously treated, but as subjects for a mixed house, be it stove, intermediate house, or greenhouse, they are certainly more difficult to keep in health than many other genera. They are, as a rule, very susceptible to changes in temperature or other atmospheric conditions, and this alone makes them unsuitable for growing in a house devoted during winter to a miscellaneous collection of plants, although it would be easy to name many cool house Orchids that would get along fairly well there. In choosing a house then for these Orchids a little thought may with advantage be given to the conditions under which they grow naturally. High up on the mountains the climate is moist and mild all through the year, and does not vary much in temperature; therefore high summer and low winter temperatures must be avoided. The day and night, too, being probably nearly equal, it is obvious that during winter every ray of sunlight must be made the most of. It is for this reason that cool *Orebid* houses ought not to be built in heavily shaded positions, or anywhere in fact where the light is much subdued. The lean-to house behind a north wall so often recommended is all very well for the plants during the summer, but in winter they simply sicken from want of daylight. Another point sometimes lost sight of in their winter treatment is the need of fresh air moving about them. From a dislike of fire-heat many cultivators keep their cool house Orchids shut up like prisoners during the winter, and if a little ventilation is put on when the sun is bright, it is taken off early to make the most of the sun heat. Now only a little thought is necessary to prove the fallacy of this reasoning. Had the pipes been kept just warm the house could be opened earlier, thus drying up the night moisture and enabling the cultivator to use more water about the house, giving each plant that requires it a good soaking without any fear, and keeping the ventilators open until quite late in the afternoon. This is the way to make the most

of the sun-heat, or more properly to utilise the sun's action. But if fire-heat is valuable when the days are bright and the nights cold, it is doubly so during the spells of damp, dull weather so frequent at this time of year, for by its help the cultivator is enabled to keep the ventilators open both night and day, and at the same time the temperature from unduly falling. Briefly then, what these Orchids require at this season is a constant and unvarying temperature, copious supplies of fresh air on all possible occasions, and full exposure to all the light obtainable. To aid in this latter, as well as to ensure the full advantage of the air currents, the plants are usually elevated on inverted pots, instead of being placed on a flat stage, and this also admits of the syringe being freely plied between them in bright weather without wetting the surface of the compost. In low span-roofed structures with a central path and side stages, this mode of arranging the plants is an admirable one, but, in doing so, the plants nearest the path must be kept on a level with those nearer the eaves of the roof, and not, as is too frequently the case, a foot or more below them, or the amount of light obtained by the former will be but little. With regard to

#### WATERING

at the root, the quantity needed will depend on the state of growth. Although with one or two exceptions, *Odontoglossum* do not require to be dried off during the winter, most of them require less water than in the summer months, especially such as have finished up their pseudo-bulbs. All the *O. crispum*, *Pescatorei*, *luteo-purpureum*, *triumphans*, and similar species usually root freely in late autumn, and, taking advantage of this circumstance, most growers repot these in September or October. It is these plants just rooting well into the new compost, and in many cases swelling up their bulbs, that require most water now, while others with their pseudo-bulbs, quite matured and not as yet showing the spikes, will need a somewhat diminished supply. The smaller growing members of the genus, as *O. Cervantesi*, *O. Rossi*, *O. Oerstedii* and similar kinds, require a good deal of care in watering. They all delight in moisture, and being of small growth are easily injured if kept dry for any length of time, but are none the less very easily overdone in this respect. What they all like is a very thin layer of compost, and then there is little fear of their being over-watered if ordinary judgment is exercised. The vexillarium and similar types now grouped under *Miltonia*, are still occasionally styled *Odontoglossum*, and these require a fairly liberal supply, the roots being active all through the winter, collecting moisture for the development of the new growths. *O. grande* may be noted as requiring less water than the majority, the flowers being mostly over and the plants at rest, the same being the case with *O. Inseleyi* and *O. Schleiperianum*. *O. Edwardi* is easily over-watered at this season, for though some of the plants are already forming young growths, these and the advancing flower-spikes procure a good deal of nourishment from the large pseudo-bulbs. The distinct and beautiful *O. Londesboroughianum* is not everywhere a success, and this is frequently the result of the loss of roots consequent on injudicious watering. The grower of the best plants of this remarkable species I ever saw assured me that from the time the blossoms were past until the new growths started, the quantity of water these received was practically *nil*, and the same treatment holds good in respect to *O. citrosimum*, which from the present time until the flower-spikes appear should be kept perfectly dry at

the roots. The plants will shrivel a good deal without doubt, but will soon plump up when they are again watered. H. R.

**Cypripedium names.**—During the last four or five years at least 500 new names have been added to the *Cypripediums*, and it is a question whether these are all sufficiently distinct. Take, for example, *C. Ceres*, *C. Fascinator*, *C. Medea*, and *C. Marchioness* of Salisbury, the result of crossing *C. Spicerianum* with *C. hirsutissimum*. Surely, however distinct, it might have been considered that the original name of the cross, *C. Charles Richman*, should have remained. My experience is that out of fifty plants obtained from the same pod of seed one could get at the least forty varieties, some with a few more spots and others a shade or two darker in colour. Is this, however, sufficient distinction to merit a new name? The Orchid committee seems to think so. I am quite aware of the difficulties under which the committee are placed, but they have a code of rules which appear to be followed as much in the breach as in the observance. I believe the rules are laid down that all exhibits shall be named in Latin, and a reference be given to the botanist who has described the plant. This latter part might certainly be cut out in respect to hybrids, for the Kew authorities decline to deal with them, but in the case of species they are always willing to render every assistance. If the Latin naming was strictly adhered to, it would do away with useless and unnecessary names. The committee, by setting their faces against complimentary names, such as *Charles Canham*, the *Hon. Mrs. Astor*, &c., would benefit all lovers of Orchids.—STELIS.

**Cypripedium insigne Maulei.**—This is one of the best varieties of *C. insigne*, and the parent of many fine hybrids. Originally selected from an importation of the type by the late Mr. W. Maule, of Bristol, it has found its way into a great many collections, though it is by no means a common Orchid. The leaves are rather more erect than those of the type, and deep green. The flowers are large, the petals and pouch being similar to those of the type, the dorsal sepal much superior. The upper portion is pure white, with large spots of purple, the lower being also margined with white, the spots being brownish purple. Like the type, it is a very free grower and abundant bloomer, lasting many weeks in perfection.

#### LÆLIA ALBIDA.

This must be a very plentiful Orchid in its native habitat or it must have become extinct long ago, so many hundreds of plants having been imported into this country only to flower fairly well for a year or two and then be thrown away. It is a great pity more care is not taken with this lovely plant, for its extinction would mean a serious loss to Orchid growers. It is one of those species that seem to do well for a time in most places, afterwards going back by degrees; yet good plants are occasionally met with that have stood for years, and the question arises how best to treat them to bring about this satisfactory state of affairs. One cause of failure, and undoubtedly a very frequent one, is allowing the plants to become overrun with insects, especially a soft white scale. This troublesome pest, if not kept in check, soon paralyses the strongest plants by drawing all the juices from them. On the first signs of its attacks let the plants be thoroughly gone over leaf by leaf, carefully examining the axils and the basal sheaths of the pseudo-bulbs; under these and about the rhizomes it is pretty sure to congregate. The insects will not all be killed perhaps at the first attempt, so the leaves had better be again sponged in about a fortnight's time, and by this means one of the difficulties of its culture will be overcome. A

more arduous task is how to provide the right kind of atmosphere and a suitable temperature for it. A house kept only a little warmer than the *Odontoglossum* house, a free circulation of air and plenty of atmospheric moisture, are the most likely to be suitable, and the plants may be grown on large rough blocks, or in small shallow pans. In either case they must be kept well up to the light, and a full supply of water is needed to the roots while growing, this being lessened, but not entirely withheld, during the resting period. Care must also be taken that the plants do not grow away from their rooting medium, roots growing only in the atmosphere not being sufficient to sustain the growth. The typical

*LÆLIA ALBIDA* produces erect scapes of flowers, each bearing five or six, the sepals and petals being white, the lip also white, suffused with rosy purple, and having several lines of yellow through the centre.

*L. A. BELLA* is a large-flowering and handsome form, similar to the type in shape, but having all the segments tipped with rosy lilac, and the same colour lightly suffused on the petals.

*L. A. SULPHUREA* is of a yellowish tint in ground colour, the lip being soft rosy magenta, with orange centre. All the varieties are natives of Mexico.

**Masdevallia ignea.**—Several plants of this pretty species now being in flower give an opportunity of comparing the varieties, and very beautiful some of these are. The typical flower is about  $1\frac{1}{2}$  inches across, of a bright orange-red, and, being very lasting, contributes largely to the winter display. Considerable care is necessary in watering these Orchids at this season, especially if they have been long in the pots and the compost consequently at all close. While easily injured by over-watering, the opposite extreme must be guarded against as equally injurious to the well-being of the roots. *M. ignea* is a native of New Grenada, whence it was introduced in 1871.

**Cypripedium concolor.**—This delightful little species is now in bloom, the pretty spotted flowers having a great attraction for lovers of *Cypripediums*, and contrasting well with the handsomely-marked foliage. *C. concolor* likes a warm house, and must be grown in a shady, moist position out of the reach of draughts. The pots must be thoroughly clean and well drained, and the compost generally used for it consists of peat fibre, loam, and Sphagnum, with limestone added in lieu of crocks and charcoal. There is considerable variation in the flowers, those of the type being creamy white, with rosy crimson spots, while the variety *sulphurea* is wholly yellow.

**Oncidium ornithorrhyncum.**—The light and graceful spikes of this pretty *Oncid* are admirably adapted for cutting, the plants are useful for grouping, and it is in short one of the best of the small flowered section. Being by no means fastidious in its cultural requirements, it is a species that may be taken in hand by anyone having a little experience among Orchids and is sure to give a good account of itself at flowering time. The individual flowers are small and rather insignificant, but when viewed collectively they are very beautiful, the colour a soft rosy-purple; they last for some time in good condition and are very sweetly scented. It is best grown in a house intermediate between the *Cattleya* and cool houses, or if this is not at command it will get along very well at the cool end of the former. A shady position and abundance of atmospheric and root moisture are essential to its well-being, and during winter it must not be over dried. Three parts of peat to one of Moss will suit it well as a rooting medium, and only a thin layer of this is needed over abundant drainage. It is a native of Central America, whence it was introduced in 1826. The flowers of the variety *albiflorum*, a rare and very desirable plant, are pure white with the exception of a yellow crest.

*Zinnia elegans double stipel.*

*Zinnia elegans double pompon.*

*Zinnia Mexicana.*

*Zinnia elegans double Lilliput.*

*Zinnia elegans nana double.*

*Zinnia Mexicana double.*

*Zinnia elegans double.*

## FLOWER GARDEN.

## ZINNIAS.

It would be necessary to go back to a somewhat distant period in the past in order to come upon the date at which *Zinnia elegans* (that is, the single-flowered typical species) was introduced into Europe. This species, with flowers of various colours, red, scarlet, purple, white, and yellow, was for very many years cultivated in flower gardens. In the year 1858 a new form of it made its appearance under the name of *Zinnia elegans flore-pleno* and created a great sensation. This variety flowered for the first time with M. Grazeau, nurseryman, at Bagnères, amongst other plants raised from seed received from the W. Indies. The first plants raised from this seed were sold in France by the firm of Vilmorin-Andrieux and Co., Paris, and in England the establishment of Messrs. Carter raised plants from seed obtained from the same W. Indian source. Great was the surprise caused by the first appearance of the flowers. The *Gardeners' Chronicle* of the period relates that "A box received from Paris, when opened, appeared at first sight to be filled with a new race of double Dahlias, but when the contents were unpacked and examined more closely, they were found to be a collection of Zinnias of the finest form and colour." The new variety proved to be a great success, and soon found its way into the gardens of all classes, notwithstanding the rather stiff habit of the plant and the somewhat monotonous regularity of the flowers, with their rigid, imbricated petals of slightly metallic aspect. At first the seeds when sown yielded a pretty large proportion of double-flowered plants; some were only semi-double, and the form of the flowers was more or less flat, or more or less bulging, but by rigorous selections the proportion of double-flowered plants was soon increased, and at the same time the form of the flowers was greatly improved. As for the single-flowered typical species, there being now no great object for its retention in gardens, its culture was ultimately discontinued altogether, so that at the present day it would be difficult to find it grown anywhere outside of botanical gardens. The double-flowered *Zinnia elegans* is now too well known to require any description here. The object of the present article is rather to acquaint the reader with the different stages or phases of modification and improvement through which the original variety of 1858 has since then passed. The first improvement obtained by culture was in the form of the flower, which, from being flat, gradually became more and more bulging or rounded, so that at present in some cases the length or depth of the flower-head is equal to its width. Next a great variety of colour was obtained, ranging from white, through yellow, red, and purple to deep violet, while more recently a variety has been raised which has the flowers striped and variegated somewhat after the fashion of the Flemish Pinks, Italian Verbenas, &c. A few years since a variety of *Zinnia elegans* with large double flowers was raised and fixed by a French grower, the plant being stouter and more robust in all its parts, and growing to a height of from 2 feet to over 2½ feet. The flowers of this variety are very broad, but are rather flat (although some improvement has already taken place in this respect), with long, imbricated, and slightly reflexed petals. They range in colour from flesh-white to violet, and the variety being remarkably vigorous in growth is very effective when grown in flower beds or as an edging around groups or clumps of shrubs of a certain height.

Another very interesting sub-variety of *Zinnia elegans flore-pleno* is the dwarf double form, which grows only from 12 inches to 14 inches high, is very branching in habit, and has regular, well-shaped, long-lasting flowers. Like the other varieties, the flowers of this have a wide range of colour, and they also exhibit such a diversity of form as would lead one to consider them distinct varieties, for while the white, scarlet, and violet-coloured flowers are very large and flat, the yellow, purple, and salmon-pink-coloured flowers are smaller and more bulging or rounded in shape. This dwarf sub-variety is particularly suitable for flower-beds, edgings and borders. Other very interesting sub-varieties were raised some years since, notably the pompon double *Zinnia elegans*, quite a distinct form, not so tall-growing as the ordinary form and seldom exceeding 18 inches to 20 inches in height. The flowers, which are perfectly double, with narrow, closely-set, imbricated petals, are smaller, but more numerous than in the ordinary form, and are also of a more elongated, bulging shape. The plant is also more branching in habit, and is a very valuable subject for flower-beds and borders. Then there is the Lilliput double *Z. elegans*, a reduced form of the pompon double *Zinnia*, not exceeding 14 inches to 16 inches in height. The flowers, which are real miniatures, rather resemble the varieties of the very small-flowered *Dahlia Lilliput*; they are very double, bulging or rounded in shape, and have long stalks, so that they are useful for cutting and putting into vases or bouquets.

One of the great advantages of the double-flowered *Zinnia*, and of all its sub-varieties as well, is the length of time during which the plants continue in bloom, and especially the long duration of the blooming of each individual flower-head. With respect to this, it may be mentioned here that, by the prolonged successional development of the petals, which progresses from the exterior of the flower-head to the centre, the blooming of one single flower-head may continue for a month or more, a quality which considerably enhances the ornamental value of this interesting composite.

About the time when *Zinnia elegans flore-pleno* first appeared, another species—*Zinnia mexicana*, introduced from Mexico by M. Haage, of Erfurt—was already in commerce. This species, which is quite distinct, has much smaller flowers than *Z. elegans*. They are of an orange-yellow colour with a brownish conical disc or receptacle; the petals or ligules are lanceolate-oval, and the leaves are sessile, sheathing the stem, those on the upper part of the stem being narrower.

Although much less ornamental than *Z. elegans flore-pleno*, nevertheless *Z. mexicana* (*Z. Haageana*, Regel) is a very good plant. It flowers at the same time and thrives in the warmest positions and even in the driest soils, provided they are of a somewhat stiff or compact character, blooming more abundantly in proportion to the heat which it enjoys. The plant grows to a height of from 12 inches to 16 inches. A double-flowered variety (*Z. mexicana flore-pleno*) has been raised from it, which is much more ornamental and continues longer in bloom than the typical single-flowered species. This fresh gain to horticulture may be advantageously employed to form an edging to flower borders or around groups or clumps of shrubs.

**Diapensia lapponica.**—Of the plants which occur in northern regions this is certainly one of the most charming and most worthy of cultivation. In habit and aspect it somewhat resembles *Azalia procumbens*, but is of more compact and

tufted growth, forming a hemispherical cushion composed of numerous rosettes of thick, spatulate, obtuse, entire, imbricated leaves. The flowers are white, solitary, with a well-opened campanulate corolla, which is divided into five spreading obtuse lobes. Like the flowers of the Ericaceæ, they are very persistent. In the wild state the plant is found in arid, sunny positions in the northern parts of Norway, N. America, and throughout the entire Arctic circle. It covers the summit of the North Cape with carpets of vegetation, presenting almost the appearance of the Lichens with which the plants grow intermingled. The culture of *Diapensia lapponica* is not at all an easy matter, and we have had a good deal of trouble in attempting to succeed with it in our alpine garden at Geneva. We have only done so satisfactorily since we took to growing it in pans provided with numerous holes in the bottom, so as to ensure very rapid drainage. A very porous soil also is necessary, consisting of one-third leaf-mould, one-third Sphagnum, and one-third sand, together with full exposure to the sun. In England, where *Diapensia cuneifolia* (*Tryxidanthera barbulata*) is often grown for *D. lapponica*, I think the addition of Sphagnum is unnecessary, the atmosphere there being moister. The plant can only be multiplied from seed; there is no use in trying to propagate it by division, as it invariably perishes when that is attempted. The seed takes a long time to germinate—often eighteen months—but if sown when freshly gathered, it germinates in a much shorter time.—H. CORREVOY.

## THE GLADIOLUS.

I, AND doubtless other florists, have been greatly pleased and interested in the beautiful plate of handsome varieties of the Gladiolus shown at page 420 of THE GARDEN. What we do want for our gardens is a hardy type that will flower undisturbed year after year in the borders. Many years ago I tried *G. Saundersi* with others in the border, and I found it stood well for several years and flowered annually, but it did not increase much and ultimately disappeared. The soil was rather clayey. I have often longed to have the chance of growing the Gladiolus on a suitable soil such as Dean Herbert wrote about, and in which he grew his hybrid Gladioli at Spofforth. The soil, he says, was "a light yellowish loam suitable for barley." Any amateur with such soil might easily raise many varieties, such as are figured in THE GARDEN. *G. Saundersi* and other fine specific forms were unknown in English gardens when the "Amaryllidaceæ" was written. The author had to do the best he could with *G. cardinalis*, *blandus*, *carneus*, *inflatus* and *tristis*, yet from these species he produced what he termed "hybrid intermixtures" of every shade of colour, from white to scarlet, rose, coppery and blackish purple, and some exquisitely speckled in consequence of the cross with *G. tristis*. The point most worthy of notice is the fact that in Herbert's garden the clusters of bulbs stood out in the open garden for twenty years with the precaution of covering them with leaves from November to March or April. He advised sowing the seed in pots, giving the young plants shelter until they were pretty strong, "and then turn out the ball unbroken into the border, where they will produce a crowded nosegay of flowers of various shades of colour." I do not know any garden flower more easily raised from seed or which can be cross-fertilised with less difficulty. Why, then, need amateurs wait for new varieties to be raised for them in France or America? The great charm of gardening, to my mind, consists in anticipating the time when seedlings raised from cross-fertilised seed will produce their flowers. *G. Saundersi* has been in the country for about thirty years; as a

species it is very distinct, and the fine varieties alluded to in THE GARDEN have abundantly proved its capabilities to produce fine garden varieties. When Mr. Cooper was collecting for the late Mr. Wilson Saunders he introduced two other very distinct species besides *G. Saundersi*, the most curious being *G. dracocephalus*, the flowers being closely striated with dull red-purple, and as many as five and six of them open on the spike at one time. *G. Cooperi* is also most curious, the flowers marked with purple-red on a yellowish base. When the last of the three (*G. Cooperi*) was figured in the *Botanical Magazine*, Mr. J. G. Baker wrote (see *Bot. Mag.*, tab. 6202): "Three very striking new species are now established in our gardens (alluding to the three named above), enlarging materially the ground-work upon which hybridisers can carry forward their experiments"—a useful hint which has but partially been taken notice of. Since that time *G. Quartinianus*, yellow flushed with scarlet, has been introduced; also the following: *G. Kotschyanus* from Afghanistan, quite distinct in character, the flowers bright lilac-purple; *G. Watsonioides* from Mount Kilimanjaro, the flowers very distinct with a curved tube and bright scarlet in colour. Lastly, the true *G. oppositiflorus* has been re-introduced and has flowered in the Royal Gardens, Kew. This is doubtless one of the parents of the beautiful garden varieties so much improved in English gardens by Mr. Kelway, of Langport; but hitherto all the improvement has been in one direction until the *G. Lemoinei* section was introduced, the exceedingly beautiful varieties Mrs. Beecher and Ben Hur being evidence of the immense improvement produced in a few years. The yellow varieties raised from *G. gandavensis* have hitherto been of poor constitution, but it is probable if *Gladiolus Quartinianus* was used both as a seed and pollen parent, more constitutional vigour might be infused into them; although it is a fact that the yellow colour of the flowers is transferred to the foliage, or the foliage acts upon the flower in some way, so that any varieties of *Gladioli* having yellowish flowers seldom continue long in good health. The seedlings are so easily raised that no one need be afraid of obtaining some measure of success. Dean Herbert's plan may be tried, or the seed may be sown in the spring in flower-pots, and the seedlings pricked out into other pots, but the safest and easiest way is to sow the seed very thinly in 6-inch or 7-inch pots, say about the end of March; plunge the pots in a gentle hotbed and the young plants will appear in about two weeks. To prevent their drawing up weakly, admit air freely to the frame, and in May the light may be pulled off whenever the weather is fine. The plants will grow splendidly and form nice corns strong enough to flower next year. The plan of turning out a potful of plants into the open border does not commend itself to a careful gardener, as the weaker plants may be destroyed in the struggle for existence, and if a specially fine variety should be produced, it might be difficult to separate it from the mass of corns without injuring many of those remaining. It is certain that in time the weaker would have to give way to the stronger, and the most vigorous varieties might not possess the finest flowers. The better plan is to separate the bulbs and plant them in rows, forming a bed of them in the flower garden, or if round clumps or clumps of irregular form are desired in the herbaceous border, they may then be planted in the spring, allowing a space of 4 inches to 6 inches from each bulb. If the soil of the garden and the climate are favour-

able, it may be well to try some of them out in the open borders all the year round. Wet districts would be unfavourable unless something was placed over them to throw off the water; mulching with decaying leaves would help to keep out the frost, but the leaves would retain wet. A cloche over the round clumps would be the most efficient protector. If the bulbs are lifted and stored, they should be placed where frost cannot reach them, and where they do not dry up too much. They should of course be well dried before being stored away.

J. DOUGLAS.

#### FLOWER GARDEN NOTES.

USEFUL FLOWERS FOR PRESENT PLANTING.—If notes were taken from time to time of any specially useful flowers, now is the time to plant, and even if no great amount of space is available there are few places where room cannot be found for at least a few things that are in their respective seasons either of great interest in the open air or valuable as cut flowers. An instance of specialities may be cited in those white varieties of different species that are always in great request in comparatively rare plants that furnish flowers of very graceful habit, those flowers that stand exceptionally well in water, and those again that can be produced easily in quantity and that can, therefore, be recommended for special seasons of the year. In the case of white flowers one finds them in such plants as some of the *Achilleas*, *Pyrethrums*, *Antirrhinums*, the giant white *Columbine*, and later *Spireas*, *Phloxes*, and the white Japanese *Anemone*, all of which can readily be increased by cuttings or division. Of plants with graceful flower-spikes that well merit cultivation, I may mention in their respective seasons such things as *Heucheras*, *Mentretias*, *Sisyrinchium*, the comparatively new *Tiarella cordifolia*, and some of the *Saxifrage*s. Several of these may be planted in beds of deciduous shrubs, and will make a pleasing feature in connection with the same. *Mentretias* and *Sisyrinchium*s, for instance, as also *Gaultonia candicans*, I have grown for a long time among the hardy deciduous *Azaleas*. An enumeration of those flowers that stand well in a cut state would include many things already mentioned, besides the *Day* and *Peruvian Lilies* and other easily grown plants. Things to be planted in bulk for special seasons of the year must be grown to meet the requirements of different places. Besides *Roses*, I should be inclined to place among the most useful things *Polyanthuses*, *Daffodils*, *Carnations*, and *Starworts*. The time for planting *Daffodils* to secure a good display for the current season is getting over; indeed, many of them are well through the ground, and the earliest varieties have received a good mulching of leaves where such treatment is practicable. There are, of course, many other things among the herbaceous plants that would be found useful. I have, however, enumerated a few that are at once easily obtainable and easily grown. The planting should be well done, and in the case of gross feeding plants, as *Puonies*, or those that once planted may be looked upon as fixtures in their respective situations, as *Peruvian Lilies*, the ground must be thoroughly and deeply worked, and a bit of really good manure being ready to hand, a liberal proportion may be added as the work progresses. In all cases where the plants specified in the above note have not been tried, I should strongly recommend that a start be made with at any rate some of them, the display made and the amount of flowers available for vases will amply repay the time and trouble.

CARNATIONS.—Is layering beneficial to Carnations was the query at the head of a note in last week's GARDEN, and I should most decidedly answer in the affirmative if quality is required. The desirability of retaining old plants, pegging down shoots and allowing all to remain may be conceded where a mass of bloom is required, and, indeed, I always leave a bed for a couple of

seasons, but have found the best flowers are obtained from strong layers planted in October in a bit of good soil. The necessity for replanting is I think apparent when one considers the dense mass of roots furnished by healthy plants; they must exhaust the soil quickly, the surface soil one is able to put on has not the holding power to carry plants through the season like deeply-dug, well-manured ground. Neither have I ever found in the case of the old crimson *Clove* that the retention of old plants is a preventive of disease, where this is locally troublesome both old and young plants have always been equally attacked. A great feature towards success is undoubtedly early layering and a close attention to the layers right away to planting time, so as to secure thoroughly well-rooted stuff; poor weakly plants are sure to winter badly. Our soil is rather on the light side, and I generally find it advisable to tread the borders well before planting. There is no doubt about the abundance of bloom furnished by two-year-old plants, and where we keep these over only a few layers are put down from each plant. As soon as these are taken away the soil gets a slight pricking up with a fork to the depth of about 1 inch, a good mulching of peat Moss or Mushroom manure is put on, and the shoots being evenly distributed all over the bed, are then pegged down. It may, I think, be taken as a fact that the majority of hardy plants throw flowers that are larger and of better quality from young stock; at least, this is so with *Carnations*, *Pinks*, *Violas*, *Deronicums*, some of the *Campanulas*, &c., to name only a few of dwarf habit.

CHIMONANTHUS FRAGRANS.—This, thus early in the season (December 1) is the feature of the flower garden, if we include in that term, as I think we ought, all beautiful shrubs and wall plants, as well as border flowers. This early flowering, although in a sense welcome, is not altogether desirable, from the fact that whilst in the bud stage the *Chimonanthus* will resist any ordinary amount of cold; this is not the case with expanded flowers, and so instead of having them fully developed at this time I would rather see them remain in the bud stage until after Christmas. They open then slowly, and after the break up of the severe frost will last in perfection a long time. Writing of scented flowers, reminds me of a disappointment experienced this summer. Wanting a few of the *Carolina Allspice* last winter for a particular corner, I ordered *Calycanthus floridus*, under the impression that this was the highly scented variety, but find the flowers of the shrub received and planted are absolutely scentless. Was I wrong in the nomenclature, and if so, what is the correct name, and if not wrong, what is the variety sent? I shall be very glad if anyone well acquainted with the shrub will reply, as the form to hand is worthless in comparison with the variety with the powerfully scented flowers.

E. BURRELL.

LAYERING CARNATIONS.—My experience of the endurance of *Carnation* plants on the stiff Thames Valley clay at Bedford was very different from that which "E. J." finds at, or about, Hampton. The soil there, however, is very different from the clay at Bedford; indeed, if deep and stiff, yet it is of a black, porous nature, and *Carnations* might be expected to thrive upon it well. On the Bedford clay were plants not layered, and this is in reference to hardy border varieties, so called, they would die wholesale, either the first or second winter. The soil being so heavy, water, after rain, would stand about the stems, thus promoting disease and rot. It was sometimes possible to help the plants through a winter by top-dressing them somewhat mound fashion, so as to throw off some of the water and protect the stems. Still, were not layering regularly performed there would have been few *Carnations* left alive from year to year. When *Carnations* are grown on light porous soil they will do well for many years, but even in that case it would be unwise to ignore layering of some of the strongest growths, so as to ensure the perpetuation of the stock. That would still leave some other growths

to carry blooms the following year. Were it possible it would be a good plan to have plants grown in the flower garden specially to produce flowers, and others in nursery quarters specially for layering. Very much of the success which attends layering is due to the time at which the work is done, and the kind of soil it is done in. Layers will root far more strongly when laid early. They may then be lifted and replanted in October, and to make an effect should always be in clumps, thus getting well established before the winter sets in. In light soil, too, they invariably root quicker than in clay, even though some sandy or light soil be added when layering is done. Of course, for all ordinary trade purposes of increase, layering of the growths is absolutely essential.—A. D.

—“E. J.” in his article *re* “Layering Carnations” (p. 425) refers to the variety *Germania*. This district is too cold, or the soil is unfavourable for it in the open air, but grown in pots under glass for early blooming, I can quite bear out “E. J.’s” estimate of it. Yearling plants potted firmly into large sixties will produce a single flowering spike during the spring, but at the same time four or five stubby lateral growths will be formed. The plants if afterwards potted on after blooming into 6-inch pots, will each carry four or five flowering growths, which bloom splendidly.—A. J.

—I think that the remarks on the above subject by “E. J.” (page 425) require modifying. It is no doubt possible to have a better show from plants two years old than from newly-planted layers. Yet to speak of doing away with layering seems to me to be going to the opposite extreme. I have seen two-year old plants flowering splendidly, but after the second year they get leggy, and unless skilfully tied into shape they have a very untidy look. It is not a bad practice to layer all the strongest growths after the second year, and regulate them so that they may remain and flower without taking them off the old stem, or if the old stool is cut away and rooted up, the space can be filled up with fresh soil and manure and will be ready for layering into again. I should, however, prefer keeping to the old practice of taking the layers up and keeping them in pots until February. Almost all plants become weaker with age, and Carnations are no exception. The only way to maintain a strong healthy stock is to propagate annually, and with Carnations there is no better method of propagation than layering. Seedlings are now extensively grown, and they make a fine show. A large percentage will come double, but the colours cannot be relied upon, and therefore the only way to have beds of distinct colours is to propagate either from selected seedlings or to keep to the most useful named sorts. With regard to *Germania* making a better show the second year I quite agree, for I find even in pots that older plants are preferable and will produce equally good blooms in much larger quantities. The way planting is done has a good deal to do with success in growing Carnations. Where the soil is loose and light it should be pressed firmly, always avoiding planting when the ground is in bad condition.—A.

**The weather in West Herts.**—The changes in temperature during the past week have been considerable. On the 5th inst. the shade temperature rose as high as 55° in the warmest part of the day; whereas only three days later it at no time exceeded 39°. During the night preceding the 5th the thermometer in the screen fell only to 49°—making this the warmest December night for seven years. Only two nights afterwards the same instrument fell to the freezing point, and on the two following nights the thermometer exposed on the lawn registered respectively 8° and 9° of frost. At 1 foot deep the temperature of the ground at the present time stands at 30°, or about the average reading for the month at that depth. A moderate quantity of rain has fallen during the week, and on the early morning of the 7th enough snow was deposited to nearly cover

the ground. The wind was very high throughout the 5th; indeed, for the twelve hours ending 5 p.m. on that day the mean velocity amounted to 36 miles an hour. It was highest between 10 and 11 a.m., when a velocity of 38 miles was reached—direction, west. This is the strongest gale since March 24, when the record for a single hour reached 44 miles. Considering the time of year, the past week must be regarded as a sunny one, the average daily duration of clear sunshine amounting to about two hours. On the brightest day the sun shone for altogether four and a half hours.—E. M. *Berkhamsted*.

## BOOKS.

### A HISTORY OF GARDENING IN ENGLAND.\*

MISS AMHERST has done her work in this in a very conscientious and thorough manner, and we wish we could say the same of Mr. Quarritch's part of it. The “History of Gardening in England” begins with the Roman occupation. The Romans were skilled gardeners, and in a climate like that of Britain—which, according to Tacitus, was suitable for the cultivation of all vegetables and fruits except the Olive and the Vine. After the Romans left, Britain became the prey, in turn, of barbarian invaders, under whom gardening, with other peaceful arts, died out, and horticulture only revived with the spread of Christianity and the establishment of monasteries some centuries afterwards. The monks were great gardeners, their life within walls and the reverence which was accorded to the monastic life kept them free from the turmoil which distracted the peasantry without, while it enabled them to perfect the knowledge of gardening which they had obtained not only from books, but from their intercourse with the Continent. The existence of gardens or orchards in the eleventh and twelfth centuries, and a few of even earlier date, is only proved by reference to monastic records. In those days plants, not being vegetables for daily food, were chiefly grown for their medicinal virtues, and flowering plants were rarely cultivated for their beauty. Still, Roses, Lilies, Violets, Peonies, Poppies and the like, having medicinal uses, would not be excluded from the garden. In the Middle Ages the use of flowers in the services of the church and for the adornment of altars, candles and shrines was very general. In the twelfth and succeeding centuries gardens were not only found within monastic precincts, but were also attached to many churches and chapels. Such gardens were under the care of the sacristan, but after the Reformation the decorating of churches was considered unlawful, and they fell into disuse or were appropriated to other purposes.

An important part of the monastic garden was the cultivation of Vines; bishops and nobles also had their vineyards, notably the Bishop of Ely's at Holborn and the Earl of Lincoln's hard by. They must have been sour Grapes, however, for we are told that from the latter vineyard about fifty gallons of verjuice were sold in one year (1295-6). In Smithfield a vineyard was planted by Geoffrey, Earl of Essex, about the same time. Passing from the monastic garden, there appear to have been gardens round Carlisle and outside the castle walls in the year 1173. In the reign of Edward I. there were a garden and vineyard at Westminster belonging to the king, and Henry II.'s garden at Woodstock, with the labyrinth which concealed the Bower, is known to most people in association with the tragic fate of fair Rosamond Clifford. From very early times such a labyrinth formed part of nearly every garden of importance. Windsor had its garden from the first, and a garden and orchard for profit for which the constable of Windsor was responsible, and there is an entry in the account of Walter Hungerford,

\* “A History of Gardening in England.” By the Hon. Alicia Amherst. Bernard Quarritch, 15, Piccadilly, W.

Knight, Constable in 1419-22, in which he declines to be answerable for the fruits of the orchard and vineyard which were eaten by the ladies and others of the king's household. Besides the royal gardens at Westminster, Charing, and the Tower, there were other gardens round London, but chiefly, so far as there is any record, belonging to monastic houses. Large quantities of Pears, Apples, Nuts, and Cherries, as well as Grapes, were sold from the gardens in Holborn. Many of the Pears were of French origin, the Caloe, or Caillou, the Pesse, or Passe Pucelle, the St. Rule, probably named after St. Regolo, Bishop of Arles. There were also the Martin, the Sorell, the Chasteys, and the Gold Knops Pears, the prices varying from 4s., 2s., 3d., 10d. the 100.

### THE FOURTEENTH AND FIFTEENTH CENTURIES

are remarkable for the growth of a class of farmers around whose farms and manors gardens and orchards were planted. The poorer classes would seem to have depended chiefly on vegetables for food. The beginning of this period was the time of the fearful plague known as the Black Death, and doubtless gardening suffered with other industries from the neglect into which product of human energy was allowed to fall. In spite of this, however, by the end of the fourteenth century every small manor or farm could boast of a garden. Then came the check caused by the Wars of the Roses. In the Middle Ages the idea of a garden solely for beauty and pleasure was a secondary consideration, and the kitchen garden—as we now call it—was the only one attached to the house. About the beginning of the fourteenth century great attention was paid to grafting, and it was considered an essential part of a husbandman's education. Gardens then were usually square enclosures, bounded by walls of stone, brick or daub, or by thick hedges. There were generally two entrances, one giving access from the house and the other leading to the orchard or meadow. Miss Amherst devotes a chapter to early garden literature. Coming to Tudor times, we find freedom from internal wars favouring a new style of domestic architecture and a greater play of fancy in the garden. Trellis railings already in fashion remained in vogue for many years. Then, also, topiary work made its first appearance in England. This “art,” it is said, was known to the Romans. In Tudor times, also, the mound, or “mount”—hitherto found only in monastic enclosures—became an important accessory of the garden. The mound served as a look-out over the surrounding country, and was often surmounted by an arbour, which was sometimes of considerable length, in the form of a gallery. Elizabeth of York, consort of Henry VII., had one of these “roosting-places”—as they were sometimes called—made for her in the little park of Windsor. At the beginning of the sixteenth century “knotted” flower beds were added to the straight beds in the garden; these knotted beds being laid out in complicated geometrical patterns, and by the year 1520 they were in common use. Contemporary writers mention the flowers that were cultivated in these “knottes,” viz., Acanthus, Asphodel, Auricula, Bachelor's Buttons, Anemone or “Blites,” Cornflowers or “Bottles,” Cowslips, Daffodils, Daisies, “French broome,” Gilliflowers (three varieties), Hollyhock, Iris, Jasmine, Lavender Lilies, Lilies of the Valley, Marigold, Narcissus (yellow and white), Pansies or Heartsease, Peony, Periwinkle, Poppy, Primrose, Rocket, Roses, Rosemary, Snappedragon, Stock Gilliflowers, Sweet William, Wallflowers, Winter Cherry, Violet, and, besides, sweet smelling herbs such as Mint and Marjoram. To the number of cultivated fruits, the greatest addition was the Apricot, which probably was introduced by Henry the Eighth's gardener, Wolf, about 1524. Red Currants also made their first appearance about this time, at least they are never mentioned by the name in earlier records, and Gerard, so late as 1597, describes them as a very small kind of Gooseberry without “prickles,” of a perfect red colour. The largest supply of fruit trees came

from his orchard at Tenham, in Kent. Under Elizabeth gardening, became greatly improved.

#### THE ELIZABETHAN GARDEN

was a blending of older fashions in English gardening with new ideas from France, Italy, and Holland. This period saw the beginning of the architect's garden: That is to say, the architect who designed the house designed the garden also. Yews were much employed for hedges for sheltered walks, and the terrace was introduced. The walks were "spacious and fair," and were of two kinds; those in the open part of the garden with beds geometrically arranged on either side, and sheltered walks between high-clipped hedges, and some times "shadowed over with vaulting or arch-hearbes," when they were known as "pleached alleys." At this period many new flowers were added to the gardens. The taste for statues and fountains and ornamental streams was brought in by foreign refugees from France and the low countries. The book contains an interesting chapter on kitchen gardens under Elizabeth and James I., also a chapter on Elizabethan garden literature. Coming to the time comprised in the reign of Charles I., the Commonwealth, and the Restoration we find the garden as we have seen it under Elizabeth, undergoing few changes until the last-named period, when many beautiful features, and new and rare flowers and fruits were added to the garden and orchard. An able gardener of this period was John Evelyn, who laid out several important gardens. He was a great advocate for clipped hedges. "Is there under heaven," he asks, "a more glorious and refreshing effect of the kind than an impregnable hedge 480 feet in length, 9 feet high and 5 feet in diameter, which I can show in my now ruined gardens at Sayes Court (thanks to the Czar of Muscovy), any time of year glittering with its armed and varnished leaves." The reference is to Peter the Great, who, during his residence at Sayes, near Deptford, amused himself by being wheeled about the garden in a wheelbarrow over gardens and through hedges. At this time great attention was paid to the cultivation of Tulips, Oranges, and many foreign tender plants. Conservatories became more general and orangeries were introduced. French gardeners were invited to come over and lay out the royal gardens, and they came, and to carry out their vast ideas, trees were planted in longer, larger and bolder avenues; there were terraces and wide paths, statues, fountains and cascades. Every garden also contained one or more sundials. Under William and Mary, the French and Dutch styles of gardening flourished, and it is now that we first hear of the parterre. The next chapter is devoted to the

#### DAWN OF LANDSCAPE GARDENING,

and the lively controversies it gave rise to between the advocates of the new and old styles. Then follow chapters on landscape gardening and gardening in the nineteenth century. A valuable feature of the work is a bibliography of works on English gardening. An alphabetical list of authors' works on gardening is also given, and there is a good index.

As regards the assumption that "landscape" is but a phase of taste like any passing fashion, we should like to say a few words. It has existed ever since the eyes of men were first opened to the beauty of the earth as now when from thousands of places in England beautiful landscape views are seen across the cultivated land. It exists in the wild mountain woodland and in the forest plain, apart altogether from man's efforts and as expressed in the parks of England from Alnwick to Richmond. It is in either case, we hope, too lovely a thing to pass away from the world so long as man has any eyes to see beauty.

But if all the works of man in landscape planting were swept away to-morrow there would still be beautiful landscape on vast areas in all countries. There are ten thousand grassy lawns among the mountain pines of Switzerland, where beautiful things are seen in the landscape, as

there are on the mountains of California and Cashmere, and indeed the many other woody mountain lands of the world. Writers like Pope and Addison, who expressed so wittily their objection to the formal style of gardening, were more right than they perhaps knew, because they had not gardening knowledge enough to know how unnecessary the stupid formality they laughed at was to the working of a garden. Apart from the disposition of ground and landscape, there is the question of the arrangement of all the beautiful things of earth—flower, shrub, or tree in right or wrong ways, which is really the same question. Here there were always lessons to be learned which the poet or the clear-eyed observer could not fail to see. One cannot draw any strict line between lovely colonies of Bird's-eye Primrose in the bogs of Westmorland, the little families of Gentian by the alpine streams, the groups of Venetian Sumach cropping out of the alpine rocks, the groves of May on hill and mountain, and the stately groves of the forest plain. It is a question of degree. In planting and carrying out in the garden the same things we are simply learning a lesson direct from nature, and in no way carrying out a mere fashion or fancy.

The expression of these ideas seems to some people to imply that one must allow nettles to come into the windows, and the garden generally to be a wilderness. But having plants in natural forms does not in the least prevent one from making a straight walk along a straight wall, or from having the necessary wall protection for one's house. To be possessed of the natural and artistic idea does not prevent us from using common sense in the disposition of the ground around a house.

Many people think that once given a garden wall all within it must be stiff, but that is an error. The common flat way of arranging is not in any sense the Italian or the beautiful way in England or in other countries, as we see in various countries where the presence of a wall does not prevent things being grown naturally and beautifully any more than the walls of a room in Japan prevent the Japanese from preserving the natural lines of flowers, or a European lady from arranging her flowers in simple natural ways. There is a difference between the great teacher Nature and the chinoiserie of decorators. In those days the gardener was the cypher who carried out the ideas of the architect, armed with the shears and occasionally with a scythe and a high ladder, when the poor clipped trees extended for miles as at Versailles; or sometimes he had a pot of paint to colour beds of bricks and stones (as in our own time at Kensington). The landscape art was not invented by Kent or Brown or any of those old writers; it was the simple aspiration after truth and nature. As Addison wrote (p. 238): "I do not know whether I am singular in my opinion, but, for my own part, I would rather look upon a tree in all its luxuriance and diffusion of boughs and branches, than when it is cut and trimmed into a mathematical figure; and cannot but fancy that an orchard in flower looks infinitely more delightful than all the little labyrinth of the most finished parterre." This view is not merely a question of taste, but absolutely true, as anybody who has paid any attention to Art knows.

Having disposed of the garden from the historical point of view—and there is no doubt that the authoress has done her best with the original documents and sources of information at her disposal, we cannot help saying that the publisher has not, we think, done his work so well. A publisher who has passed so many beautiful books through his hands as Mr. Quaritch must know that these "processes" in many cases give no idea of the things they represent, and that they are better omitted if cuts cannot be reproduced better than, for instance, the one of Burghley (p. 206) and, indeed, many other cuts in the book, which are not right either in tone or distance, or in clearness. The process also means the use of heavy-clayed and glazed paper, which is so very inferior to the old paper which was so light in

the hand. These heavy-clayed papers even interfere with the binding, as the books printed on them cannot be bound in the same secure way as in the days of real paper.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

DECEMBER 10.

TAKING into consideration the season of the year, this gathering was a remarkably good one, although in quantity there was again a falling off. The greater part of the labours of the day fell upon the Orchid committee, before which many noteworthy exhibits were presented. On this occasion *Cypripediums* predominated, there being some of the rarest kinds, both species and forms of species, as well as hybrids, to be seen. Amongst these were several of the very choicest, as *C. insigne Sanderianum* and *C. insigne Sanderæ*, two of the gems of this old species. The work of the fruit committee was comparatively light; there were a few good Apples shown, but on this occasion the honours, both in size and quality, belonged to the Onions, of which some fine examples came from two of the best known growers. The floral committee had but little more to do than the fruit committee, *Chrysanthemums* being the strongest feature, of which there was a most notable exhibit by Mr. Briscoe-Ironside, of a rich yellow variety, tastefully and effectively arranged in a vase of terra-cotta colour. Some first-rate bush plants came from another source, and also a few fine late blooms of the Japanese section.

#### Orchid Committee.

A first-class certificate was awarded to—

*DENDROBIUM TREACHERIANUM*.—A most distinct species, which at the first glance would not seem to have any or but little affinity to this genus. In its growth it resembles more a *Maxillaria* than a *Dendrobium*, the bulbs being short and stout, surmounted with a pair of leaves of great substance, but which, singular to say, appear to be disposed to partially die off. The flowers are produced from erect spikes which issue from the apex of the bulbs, each spike bearing from six to ten flowers. In colour these are of a dark vinous crimson at the base of the lip, shading off to rose at the extremities, the sepals and petals being pale rose, toning down to almost white at the tips. The plant bore three spikes of fine blooms. A noteworthy fact concerning this *Dendrobe* is that it was discovered by Mr. Peter Veitch and Mr. F. W. Burbidge in their Bornean expedition nearly twenty years ago. From Sir Trevor Lawrence's collection.

Awards of merit were made to the following:—

*MASDEVALLIA MACRURA*.—A most lovely species, both distinct and singular; the flowers each measured 10 inches from tip to tip of the sepals, being in colouring of a rich orange tint, shading off towards the extremities of the long tail-like sepals to a pale gold colour, the surface of the inner portion of the flower being profusely spotted with dark maroon spots. From Sir Trevor Lawrence.

*CALANTHE HARRISII* (*C. vestita* Turneri × *C. Veitchii*).—A charming and singularly unique hybrid, having the bulbs of the former and the flowers, so to speak, as regards form, of the latter parent, but the colour pure white, very chaste, with the faintest possible suspicion of pale rose suffusion traceable here and there; the spike is erect, and indicates greater vigour with age. From Messrs. J. Veitch and Sons, Chelsea.

*LÆLIO-CATTLEYA LADY ROTHSCHILD* (*Cattleya Warscewiczii* × *Lælia Perrini*).—A lovely hybrid, the sepals and petals fully 6 inches across, in colour a soft shade of rosy mauve, a delicate and beautiful tint, the lip at its base having a broad blotch of dark crimson-purple and darker veins, next this was a broad band of pale lemon-yellow,

which stood forth in decided contrast to the foregoing colour. From Messrs. J. Veitch and Sons.

**ONCIDIUM TIGRINUM VAR.**—A well-marked form of this *Oncid.*, with the labellum broader and richer in colour than usual (a deep sulphur shade), the sepals and petals barred with greenish yellow on a bright chocolate ground. From Mr. De B. Crawshaw, Rosefield, Sevenoaks.

**CYPRIPEDIUM ASHTONI** (*C. ciliolare superbum* × *C. selligerum majus*).—A bold and striking hybrid, with mottled foliage, and a tall spike of two flowers; the lip partook greatly of *C. ciliolare* in form, but was darker in colour, the broad petals being drooping, as in its other parent, but of a dark vinous-purple shade, with darker spots; the dorsal sepal is also of considerable breadth, with dark purplish veins on a light ground, and in shape somewhat angular. From Messrs. W. Lewis and Co., Southgate.

Botanical certificates were awarded to the three following Orchids, all from Sir Trevor Lawrence, viz., *Angraecum pertusum*, which in growth resembles the dwarfier *Aerides* or *Vandas*, with long slender spikes of minute white flowers; *Mormodes Lawrenceanum*, a distinct, if not showy species, flowers pale greenish yellow with darker veins; *Masdevallia pachyura*, a small and dwarf species, the flowers of a dark bronzy yellow with golden tips.

Baron Schröder, The Dell, Egham, sent a very choice and varied selection of *Cypripediums* (cut blooms), all of which were remarkably fine examples and of excellent colour. These consisted of *C. insigne Sanderianum* and *C. insigne Sanderæ* (two fine flowers), *C. villosum superbum*, *C. Chamberlainianum* (fine in colour), *C. Niobe* (extra strong), *C. Stonei*, *C. T. B. Hayward* (a fine hybrid), *C. southgatense*, *C. superciliolare*, *C. Spicerianum*, *C. Lceanum princeps* and *C. Lceanum superbum* (both fine), *C. Schröderianum*, *C. cardinale*, *C. Pitcherianum* (Williams' var.), *C. Galatea*, *C. Arthurianum*, *C. Charlesworthi*, *C. Harrisianum superbum* and *C. Dauthieri albino* (very distinct). To this most interesting exhibit a silver Banksian medal was awarded.

Messrs. Veitch and Sons, Royal Exotic Nursery, Chelsea, contributed an exceedingly choice group, which comprised a beautiful example of *Lælio-Cattleya Pallas* (*Lælia crispa* × *Cattleya Dowiana*), a hybrid which, as it continues to gain vigour, shows a corresponding increase in the rich colouring of the flowers, notably in the lip, which takes after *C. Dowiana*, with the fringe of *L. crispa*. *Cypripedium insigne Sanderæ*, of which two sturdy plants were shown, was in excellent character. *C. Niobe*, a charming hybrid, was also included along with *C. (Enone) (C. Sallieri and C. Sallieri nigro-maculatum)*, the spotting very dark and distinct. *Cymbidium Tracyanum*, with a bold spike of richly-coloured flowers, and *Dendrobium subclausum* (to which a botanical certificate was awarded at the last meeting) were also included (silver Flora medal).

Messrs. F. Sander and Co., St. Albans, showed another excellent group, in which the following choice hybrid *Calanthes* were very conspicuous, viz., *C. Bryan*, *C. Wm. Murray* and *C. Victoria Regina* (soft rose), each of which was grouped together in a basket, thus adding to the effect. Of *Cypripediums* there were *C. Pryorianum*, with some affinity to *C. Lathamianum*, but darker, showing also *C. villosum* farther removed. The "Oakwood" variety of *C. Calypso*, another good hybrid, as well as the extra-fine forms of *C. Lceanum*, as seen in "reticulatum," a noble variety and quite distinct, with its massive pouch and the bright green colouration at the base of the dorsal sepal and the petals; *C. James Hamilton*, with its fine dorsal sepal; *Sander's var.*, another good form of this prolific hybrid; *C. nitens* (*Sander's var.*); *C. Donatianum*, with a large flower; *C. Uhleinianum*, *C. Alcides* and *C. Clement Moore* (*C. Dauthieri* × *C. Lceanum*), a noteworthy hybrid, as well as *C. Spicero-niveum*, which in its form showed its affinity to *C. niveum*, but the colour was a shade of rose-pink, were also shown. Of *Odontogloss* there was *O. Schröderi-*

*anum*, which improves on acquaintance, the present example bearing two sturdy spikes from the same bulb. *O. nevadense* and *O. Wilckeianum* were both shown well, likewise *O. asperum*. Of botanical curiosities, a note should be made of *Restrepia attenifera* and *Helcia sanguinolenta* (silver Banksian medal).

From Mr. Bennett-Poë, Holmwood, Cheshunt, came a most suggestive and tasteful arrangement of *Calanthe Veitchi*, extra fine spikes, and of deep rose colour, and of *C. vestita rosea*, the spikes of which were also of great vigour. Both of these vars. were arranged together with good effect. *Lælia autumnalis*, fine in colour, and *Vanda cærulea*, with two fine spikes of an intensely deep cerulean blue, came also from this source (silver Banksian medal).

Sir Trevor Lawrence showed *Lælia rubescens*, a little gem, and from Mr. H. Tate, Junr., Allerton Beeches, Liverpool, came *Cypripedium insigne*, there being two distinct forms in the one pot, the more noteworthy of these was that in which the lower sepal was quite a counterpart of the dorsal one; two flowers bore this character, this being the second year in which this possible sport had been observed. Messrs. B. S. Williams and Son, Upper Holloway, showed several *Cypripediums*, including *C. Sallieri*, with extra fine blossoms; *C. insigne Maulei*, *C. Lceanum superbum*, in which the dorsal sepal was of extra size and great purity; *C. Pitcherianum* (Williams' var.), recognised as an extra fine form and a fitting companion to *Cypripedium Harrisianum superbum*. Mr. W. C. Walker, Percy Lodge, Winchmore Hill, showed *Cypripedium Charlesworthi*, with one very large flower, the dorsal sepal of which was even larger than usual; on the same spike was a secondary, but malformed flower, in which the sepals and petals were strangely commingled. *Oncidium Graveianum* without the usual bars of yellow, thus making it distinct, and *Lælia rubescens* came also from this source. Messrs. H. Low and Co., Upper Clapton, showed an attractive group that comprised a beautiful example of *Cymbidium Masterianum* and two others of *C. giganteum* in the way of *C. Traceyanum*, but paler in colour. *Odontoglossum crispum* and *O. Roezli* were both staged here; also *Cypripedium Niobe*, *C. Charlesworthi*, *C. insigne* (vars.), and *C. Lceanum* (vars.).

From Mr. Thos. Statter, Stand Hall, Manchester, came on this occasion *Lælia elegans nobilis*, bearing four flowers on the one spike, these being distinct in colour, a rich shade of dark copper, suffused with purple, and the lip brighter than usual. *L. Tresideriana*, a pretty hybrid of dwarf growth, as well as some very fine forms of *Cypripediums*, comprising *C. Lceanum giganteum grandiflorum*, the appendices to the specific name of which must speak for the variety, a very fine one were included here. *C. Lceanum superbum* (Stand Hall var.) was also staged, the pure white of the dorsal sepal being a distinctive feature here. Other kinds comprised *C. Ariadne*, *C. Niobe*, *C. plumosum*, *C. Lucienianum*, and *C. Rufus*. From Mr. Shoreland Ball, Earlscliffe, Bowden, Cheshire, came *Cypripedium insigne Sanderæ*, an extra fine flower, of rich translucent colour, *C. insigne Ballianum*, in which the spotting of the upper sepal extends through the pure white margin; and *Cattleya labiata alba*, of fine size and purity, having the characteristic blotch on the lip.

#### Floral Committee.

An award of merit was given to—

**CHRYSANTHEMUM STRESA.**—A late-flowering decorative kind that promises well for cutting at Christmas time. The flowers shown had been brought forward in heat in order to show it at this meeting. It belongs to the Japanese section, the flowers of a clear soft yellow colour. It was shown by Mr. H. Briscoe-Ironside, Burgess Hill, Sussex.

The miscellaneous contributions were very few. Mr. J. Lyne, gardener to Mr. H. F. Fierke, Foxbury, Chislehurst, was awarded a silver Banksian medal for a group of dwarf, well-flowered plants

of *Chrysanthemum Jeanette Sheehan*. This is a useful late-flowering kind, which can be had in bloom up till February. An award of merit was granted it at the January meeting of the R.H.S. this year. It is a sport from *Princess Blanche*, and its flowers are deep buff-yellow with bronzy centre. In habit, colour, and freedom there is much to recommend it. Mr. R. Owen, Maidenhead, received a silver Banksian medal for cut blooms of *Chrysanthemums*, show and decorative varieties, the exhibit comprising a number of unnamed seedlings, several of them distinctly promising, but they cannot be noted when shown under numbers, Mrs. C. E. Shea as seen in this exhibit tends to confirm the opinion that it has been very much over-rated. Messrs. H. Cannell and Sons showed a bunch of a rich yellow incurved Japanese *Chrysanthemum* named *Ashanti*, also several bunches of *Cannas*, notably *Queen Charlotte* and *Alphonse Bouvier*, and Chinese *Primulas* in pots. Sir Trevor Lawrence was awarded a silver Banksian medal for a vase of *Anthurium* spathes, arranged with their own leafage to show the value of this class of plants for winter decoration. A pan of *Primula floribunda* in profuse blossom came from the same exhibitor. Mr. C. Herrin, Dropmore Gardens, showed three well grown and flowered plants of the shrubby *Oxalis Ortgiesi*, a species not often seen. Mr. J. T. Bennett-Poë, Holmwood, Cheshunt, showed another fine plant of *Begonia Frebéli incomparabilis* carrying a number of brilliant flowers.

#### Fruit Committee.

For the time of year the exhibits were fairly numerous, and vegetables (Onions especially) were good. Most of the members of this committee were present, to express their good wishes to the secretary, this being his last official appearance at Westminster.

An award of merit was given to

**VICTORIA BORECOLE**, a very fine type of Scotch Kale from Messrs. Dobbie, Rothesay. It is a selection of their Dwarf Green Borecole, a close-growing kind, and very hardy. The committee desired it to be sent to Chiswick for trial.

Mr. Pope, Highclere Castle, Newbury, sent thirty dishes of Onions, all good, half being sown outside, the other portion having been raised under glass. The heaviest were Ailsa Craig, Improved Spanish, Rousham Park, Improved Wroxton, Anglo-Spanish, Veitch's Main Crop, Southampton Champion, Banbury, Sutton's Al Crimson Globe, Southport Globe, Lord Keeper and Improved Pinesfield. The same varieties were staged in the smaller bulbs grown under ordinary culture, but equally good. A silver Knightian medal was awarded. Messrs. Cannell and Sons, Swanley, staged a large collection of vegetables, very fine Onions in twenty lots, a few Champion Leeks and large Savoy Cabbages, with green curled Scotch Kales. The Onions were of good shape, heavy and sound, the best being Royal Jubilee, Tollingstone Park, Concord, Sandy Priza, Veitch's Main Crop, Neill's Advancer and Coconut. Beet was staged in eight varieties, but some kinds—namely Dell's Crimson—were much too coarse. Silver Banksian medal. Messrs. Dobbie staged a group of their Kales, these being noticeable for the beautiful curled leaves and compact growth. Messrs. B. S. Williams and Son sent a new seedling Tomato—Warden Park Favourite—but too much like the Old Red. It was asked to be sent for trial. Fruits of the tree Tomato (*Cyphomandra betacea*) were sent by Messrs. Curtis Sandford and Co., Torquay. Messrs. Laxton, Bedford, sent a new Apple, Bedford Scarlet, of nice appearance, but too ripe. Mr. Empson, Amptill House Gardens, sent some Apples, which the committee considered good examples of Pearson's Plate and Fearn's Pippin. Mr. Easton, Nostell Priory, Wakefield, sent three dishes of cooking Apples, fair samples of Lane's Prince Albert, The Queen (rather small), and Emperor Alexander. Messrs. Jarman, Chard, sent a new Apple, Crimson King, stated to be a late variety, but the fruits sent were past their best. It promises to be a good market fruit. Trees

were also sent to show growth, which was remarkably strong. Mr. Ross, Welford Park Gardens, Newbury, sent a new seedling desert Apple of merit, a pale coloured fruit of brisk flavour, and a good keeper. This will be useful as a good late fruit. Mr. Miller, Ruxley Lodge Gardens, Esher, sent a large collection of Apples and Pears.

At the close of the meeting, Dr. Hogg rose and proposed that—

This committee desires to record its high sense of the valuable services which Mr. Barron has rendered to it during his long occupation of the position of secretary, from which he is now retiring, and to congratulate him on the distinction of having been placed by the council on the roll of honorary Fellows of the Royal Horticultural Society. The committee will also heartily welcome him to a seat at this table, and expresses an earnest hope that he may long enjoy health and happiness, and find many opportunities for continuing to render distinguished service to horticulture and to the society.

As the oldest member, Dr. Hogg testified to Mr. Barron's great abilities, his love of the work, and the way he had done his duty in every way. Mr. Smith, Mentmore, seconded the motion. Mr. Barron, in reply, thanked those present, and feelingly mentioned the interest he had taken in the society, and his regret at leaving Chiswick where he had been for thirty-eight years. Thirty years ago that day he was appointed secretary of the fruit committee. Mr. Wythes, Syon, proposed a hearty vote of thanks to the chairman, this being the last meeting of the year. This was seconded by Mr. Balderson, Hemel Hempstead.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last, a meeting of the general committee was held at Anderson's Hotel, Fleet Street, when Mr. B. Wynne presided. The minutes of the previous meeting having been read and confirmed, and some routine business arising out of the correspondence having been disposed of, it was announced that the prize money awarded at the recent December show amounted to the sum of £51. 4s. 6d. exclusive of medals. The awards made by the arbitration committee at the same show were confirmed. On the motion of Mr. Geo. Gordon, it was resolved that in future all classes in which Japanese Chrysanthemums are required to be shown on boards, that the boards for twelve blooms be of the following dimensions, 23 inches by 21 inches, height in front 3½ inches, height at back 7 inches, holes to be 7 inches apart from centre to centre.

The annual general meeting of the society will be held on Monday, February 24 next. In 1896 the following exhibitions will be held:—Early Chrysanthemums, Dahlias, &c., on September 9, 10 and 11. Early Chrysanthemums, October 6, 7 and 8. Jubilee show, November 3, 4, 5 and 6. Late Chrysanthemums, December 1, 2 and 3. New members were elected bringing up the total for the year to 153. The following societies were admitted in affiliation, St. Botolph (Colchester), Amateur Chrysanthemum Society; the Newton Abbott Chrysanthemum Society, and the East of Fife Chrysanthemum Society.

The floral committee of this society held the last of its meetings for the present season on Wednesday last at the Royal Aquarium, when Mr. T. Bevan presided.

Owing to the lateness of the date there were only a few exhibitors, the principal collection coming from Mr. R. Owen, of Maidenhead, who was awarded a small silver medal for a collection of cut blooms on boards and in bottles comprising many novelties of recent introduction.

First-class certificates were awarded to

Mrs. R. W. E. MURRAY.—A very fine globular Japanese variety, deeply built, and very compact. The florets are narrow and intermingling, and the variety was presented in very fine form by Mr. R. W. E. Murray, of Blackford House, Edinburgh.

JEANNETTE SHEAHAN.—As a decorative and market variety this yellow buff sport from Prin-

cesse Blanche will no doubt be useful. Shown by Mr. D. Sheahan.

Goldfield, a loose decorative Japanese incurved, of deep golden yellow, was requested to be shown again. Among other novelties Mrs. C. E. Shea, white, shaded yellow; H. W. Rieman, a golden yellow Japanese incurved, of American origin, and Marie Vallean, another from the same source, a Japanese incurved, were attractive. Mention might also be made of Exposition d'Arras, Bellem, and Mme. Eugene Mercier.

### NOTES OF THE WEEK.

**Pear President Barabe.**—I have sent you today some fruits of this new late Pear. I think you will find it of first-rate quality. Pears grown in 1894 ripened at the end of January, 1895. The first time this Pear fruited with me was in 1891. It is a delightful surprise to find a Pear of such excellence ripe and in good condition at the end of January. The flesh is melting, very sweet and juicy, somewhat resembling Winter Nelis. I should think after an average normal season it would be ripe at Christmas.—WM. ALLAN, *Guntton Park, Norwich.*

\* \* A true Pear, good in form and good in flavour even compared with the excellent Winter Nelis. We say a true Pear to distinguish it from the kinds that waste precious space in our gardens, such as Vicar of Winkfield, Beurré Clairgeau, Beurré Rance, &c.—Ed.

**Grevillea Thelemanniana.**—It is a good many years since the Cape and Australian plants occupied the first place in public favour among indoor plants; yet there are still a few left behind, survivals of the fittest no doubt, and of these this *Grevillea* is one. It is a native of West Australia and was introduced in 1838. Both as a flowering and as a foliage plant it has recommendations. The leaves are bright green and are cut up into numerous linear segments. The flowers, although produced more or less throughout the year are most abundant from October on throughout the winter. They are borne in dense, pendent clusters, terminating the branches, and are of a deep rosy red at the base, where the tube of the flower is inflated, the four petals being however, of a yellowish shade. The style is conspicuous with its long, red stalk and orange-coloured stigma. When young, this *Grevillea* should be stopped occasionally to secure a bushy habit; it strikes readily from cuttings.

**Jasminum nudiflorum.**—How beautiful this Jessamine is as seen in full bloom covering a goodly space of wall at this dull season of the year! I do not mean when each shoot is stiffly tied or nailed with mathematical precision, but rather as seen when allowed comparative freedom of growth—the main stems fastened, and the young flowering shoots dangling and swaying in the breeze. I admit that during the summer it is anything but an object of beauty—far from deserving a wall at that season—but to obviate this dulness I allow *Tropeolum speciosum* to ramble and festoon itself over it, so that almost as soon as the spring pruning is done, the Jessamine is clothed with soft and delicate green leaves, and subsequently with strings of glowing bloom, intermixed and followed by a crop of lovely blue berries, and ere the sere leaves have dropped the *Jasminum* again bursts out into bloom. I would strongly recommend those who may not have as yet associated these two plants in this way—or something similar—to do so on walls or in the open—or both—and they will not regret it.—J. R.

**The yellow Scotch Pine** (*Pinus sylvestris aurea*).—The number of Pines with variegated or coloured foliage is small, and, as a rule, of no particular value. The yellow Scotch Pine is, however, an exception, and is distinctly useful for the colour it gives in winter. It is curious that it is at this season only that its foliage is noticeably different in hue from that of the ordinary Scotch Pine, and when the leaves of most evergreens are putting on a deeper autumnal

green this Pine is only beginning to assume its livelier dress. The golden colour is deep and rich, and, unlike the colour varieties of many hardy plants, does not in any way suggest ill-health. Compared in habit with the common Scotch Pine, it is dwarfer and more compact. It is, therefore, better adapted for the garden than the park. The same may be said of the varieties *pygmaea* and *nana*, both rounded, pretty bushes a few feet high; they do not differ in colour of leaf from the ordinary form. All three are propagated by grafting on seedlings of the Scotch Pine.—B.

**Thyrsacanthus rutilans.**—This beautiful winter-flowering plant is seldom seen in good condition now-a-days. It used to be largely grown and much prized for its brightly coloured flowers at this dull season of the year, making the stove and intermediate houses look gay in conjunction with *Poinsettias*, *Aphelandras*, &c. Nothing can be prettier or more graceful in its way than this plant when well grown and abundantly flowered. Plants about a foot high grown in 5-inch pots and with nine to twelve scarlet panicles 18 inches long, form splendid subjects for vases and for dinner table decoration. It also forms a very pretty picture in the intermediate house just now, the plants being slightly elevated and the interstices filled in with *Eulalia japonica*, which associates well with it. Plants should be raised from cuttings rooted in heat in spring, grown on until put into 5 inch and 6-inch pots by the middle of June. They should be placed in a cold frame during the summer and early autumn months, and given all the sunlight possible, with abundance of air to thoroughly ripen the wood. The plants should be put into an intermediate house in the beginning of October, when they will immediately show for flower. *Thyrsacanthus rutilans* is a native of Central America, and was introduced in 1851.—J. G.

**Proposed Palm house at Battersea Park.**—The Parks and Open Spaces Committee recommended: "That, subject to an estimate being submitted to the Council by the Finance Committee as required by the statute, the Council do authorise an expenditure of £2000 for the erection of a Palm house at Battersea Park, in accordance with the design prepared by the architect; and that inasmuch as the chairman of the Works Committee is of opinion that the work is one which the Works Department is not in a position to execute with special advantage to the Council, the committee be authorised to invite tenders." Mr. Beachcroft moved, as an amendment, "That the Council, having regard to the increasing demands upon it in regard to open spaces both on capital and maintenance accounts, is not prepared to undertake the cost of erecting a Palm house at Battersea Park." Colonel Rotton seconded the amendment, which was carried by 70 votes to 28.

**Gardeners' Royal Benevolent Institution.**—We are requested to state that the committee of the Gardeners' Royal Benevolent Institution have received the sum of £257 3s. 5d., being a proportionate amount of the fund raised to perpetuate the memory of the late Mr. Wm. Thomson, of Clovenfords, to be invested and known henceforth as the "Wm. Thomson Memorial Fund."

*Etudiant.*—*The Revue Horticole.* Published at 26, Rue Jacob, Paris.

**Names of plants.**—*M. Lorenzen.*—1, *Lastrea Sieboldi*, a native of Japan; 2 *Cyrtium caryotideum*, native of Japan, China, Himalayas, Neigheries, Kaffraria, &c.—*F. Allen.*—Probably *Amaryllis formosissima*, or it may be *Vallotta*.

**Names of fruit.**—*C. Quin.*—1, Pear Marie Louise; 2, rotten; 3, Glou Morceau; 4, Beurré d'Aremberg. —*Ernest Shore.*—1, Newton Wonder; 2, Golden Noble; 3, Margil; 4, Old Nonpareil; 5, Marie Louise d'Ucele; 6, Beurré Bachelier. —*J. Crook.*—Ladiv Hemiker. —*J. E. Davies.*—1, Apple King of the Pippins; 2, Pear Beurré d'Aremberg; 3, Pear Glou Morceau. —*O. R.*—Too rotten.

No. 1257. SATURDAY, December 21, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ROSE GARDEN.

## PRUNING LATE-PLANTED ROSES.

A good many Roses are planted after the new year, and it is an important question whether they should be pruned before or after planting. It is my opinion that the pruning should be done first, as the sooner this is done after the close of the old year the better the plants will flower. Plants that are pruned at the beginning of January, and not planted until the end of February or March, will have time to recover from the operation. There is no fear of those planted late, starting into growth early enough for the frost to injure them, because the check to the roots is sufficient to prevent an early growth, but there is a risk of the roots receiving a check when the branches are hard cut back just as the warmer weather induces greater activity in the roots. Plants pruned before being planted grow away more vigorously than those that have to be planted and pruned with but a short interval between. I think it better to prune but very moderately in the case of strong growers, and in the case of weak ones not at all. I have had very satisfactory results the first year from standards that have not been pruned at all both in the first and second lot of flowers, and I have not experienced any difficulty afterwards in getting the head into shape. With regard to late planting, I would prefer not to plant from the middle of December till the middle of February. Of course, a good deal depends on the kind of weather during that time, but, taking the seasons generally, Roses are better for not being disturbed during that time. Rather than plant during that time I would prefer to get the plants home, and after pruning them to lay them carefully in on a warm border, covering the roots with leaf soil or fine sandy earth. Treated in this way, the plants may be lifted at the end of February with safety, and if carefully planted will flower as early and as freely as those that are planted in the autumn and pruned in early spring. There is no doubt that a good many Roses, whether established or recently planted, are pruned too early. As a consequence the newly-made growth suffers both from cold wind and attacks of insect pests. As locality and position vary considerably, it is not easy to fix a date when the pruning may generally be done with safety. The third week in March is quite early enough in the west of England, and in colder parts of the country a week or ten days later will be found suitable.

J. C. CLARKE.

## ROSE CATHERINE MERMET.

I do not know how this Rose is grown in Paris, but I do know that there is no more suitable or beautiful Rose for pot culture, or for that matter for planting out in small greenhouses when there is no room for more vigorous growing varieties. Near to where I write there is an amateur grower who has only room enough for some half a dozen pot Roses, and his selection is confined entirely to Catherine Mermet. From these and from another plant growing in a narrow border in the greenhouse he secures a supply of Roses all the winter. The greenhouse of course is a warm one, the temperature in cold weather being 50°. I may mention the pot Roses get special treatment. Early in the summer they are pruned rather hard and

given larger pots if they want them. After this they have the shelter of a cold frame to enable the roots to get established in the new soil. After two or three weeks of this treatment they are lifted out and stood along the back of the frame, which is just high enough to prevent the sun reaching the pots. Yet most of the stem and branches have the benefit of full exposure to the sun. The excellent condition of the plants which I have seen so treated shows that the roots appreciate the cool position they occupy. I have never seen this Rose making such satisfactory growth and such clean and handsome foliage as in the case under notice. All the flower-buds formed up to the middle of September are removed, this, of course, helping the plants to get strong and well furnished with growth that will produce flowers during the winter. I am satisfied from my own practice and what I have seen in a few other places that cultivators generally keep their plants of Tea Roses in pots too small by hard pruning and confining the roots in too small pots. When such varieties as the one here referred to and Isabella Sprunt, Dr. Grill, Adam, Alba rosea, and Marie Van Houtte are grown in 12-inch or 14-inch pots, it is surprising what a number of flowers they will produce if given a suitable temperature during the winter and spring months. What such plants want is a good rest during the summer. They must be removed at the beginning of June to a warm and sheltered position in the open air and the pots plunged in coal ashes, or else some long dry litter packed closely between them. W. A. Richardson is another Rose that responds admirably to this kind of treatment if care is taken to preserve the young shoots that spring up from the bottom, removing some of the oldest growths to make room for them. The newly-made shoots produce the largest and best-formed flowers, and a few plants of these in bloom at the end of February are something to see and remember.

J. C. CLARKE.

## CHRYSANTHEMUMS.

## NEW ENGLISH CHRYSANTHEMUMS.

ALTHOUGH so many of the novelties of each season are either Continental or American seedlings, we have this year had some splendid contributions from our own raisers. Mr. C. E. Shea, Mr. Briscoe-Ironside, Mr. Weeks, Mr. W. Seward and the ordinary trade growers are proving their capacity, so far as climatic conditions will permit, to compete with all comers. Indeed, some of the triumphs of their cultural skill as exhibited this season prove that their knowledge of the requirements of the English exhibitor has served them in excellent stead in the interesting work of seedling production. Among the choicest novelties of purely English origin, the following have been shown in fine form this season: Miss Alice Love, a white Japanese; Emily Silsbury, also a white Japanese; Lady Randolph, a fine purple-amaranth variety of the same section; Lady Esther Smith, a white Japanese incurved; Mrs. Charles Blick, another pure white Japanese; D. B. Crane, a deep golden amber incurved; Edith Tabor, a grand yellow Japanese; John Seward, a Japanese, colour canary-yellow; Dorothy Seward, pale crimson, tinted carmine, with reverse of gold, also a Japanese; Mrs. J. Shrimpton, orange-yellow, streaked crimson, also of Japanese form; Lady Byron, a pure white Japanese; Piccinino, a pretty pompon, colour rosy purple, with silvery reverse; Dorothy Gibson, a reflexed variety of golden yellow; Kentish White, a Japanese incurved, the name of which indicates its colour; Duchess of Fife, another white variety; Maggie Shea, a canary-yellow Japanese; Mrs. B. Ironside, salmon-blush, an incurved Japanese of good form; Mrs. H. Weeks, the largest white Japanese shown as yet; Arona, reddish crimson, a Japanese; Mrs. Hume Long, very large, a rosy amaranth Japanese incurved; Mrs. Hermann Kless, another

Japanese of great size, colour golden bronze; Wm. Slogrove, a golden yellow Japanese, incurving in form; Olive Oclée, golden bronze, a Japanese incurved, but heavier in build than the preceding, and Miss Phyllis Fowler, a pale yellow incurved.

These are but a selection from a vast number that have come under my notice during the season of 1895. Probably many others not mentioned may ultimately prove to be equally good, but the difficulty of making a selection of the best novelties the first season is always attended with some uncertainty. Enough, however, has been said to show that our growers, both amateur and professional, are deeply interested in the work.

C. H.-P.

**Striking Chrysanthemums.**—There can be no doubt that much of the success or otherwise in growing Chrysanthemums either of the show or decorative section depends on the preparatory treatment the old stools receive previous to the cuttings being taken off. How often are cuttings taken from plants that have been huddled together as thickly as Beans in a field, becoming thereby weak and sickly. Of course, these improve when brought to the light and air, but they never can acquire that sturdy and vigorous constitution which is the only guarantee for a healthy plant and high quality blooms. Where frames can be spared the best plan is to select several stools of each sort from plants that have not been crowded together, and to place them therein in December. Here, with judicious covering in sharp weather and abundance of air on fine days, the growth will be all that can be desired. Springing up strong from the base of the stools, many of them will have a good percentage of roots to start with, and good plants will soon be formed. Although January and February are soon enough for taking cuttings for large blooms or ordinary bush plants, the end of November, or at the latest the first week in December, is the correct date for taking them for the production of fine specimen plants. Taken then, the plants are ready to pot into 6-inch pots by the middle of January, and thus have a long season of growth.—J. C.

**Chrysanthemum L. Canning.**—Though this is given in the catalogue of the National Chrysanthemum Society as a mid-season variety, its great value lies in its late blooming. Its merits in this respect were well shown in a large group consisting of this variety alone, which was exhibited at the meeting held at the Aquarium on December 3. The plants were dwarf, yet each carried a number of good blooms, which at this season of the year (and later still) are invaluable for cutting. Its value in this respect is further enhanced by the fact that though the flowers are large, they are by no means lumpy, and do not become tinged with pink as the blooms of some varieties do towards the end of the season. It is an American-raised variety and was distributed in 1888, so that it is, as Chrysanthemums go, by no means a novelty. A good companion to this appears likely to be Golden Dart, to which an award of merit was granted at a recent meeting of the Horticultural Society. It was also given a first-class certificate by the floral committee of the National Chrysanthemum Society. It appears to be a very valuable variety for cutting, the flowers standing up well on good stout stems.—T.

**New American Chrysanthemums.**—On pages 442 and 443 Mr. C. Harman-Payne gives a list of these, remarking that the incurved Japanese section seems likely to receive large additions from this list. Apparently Mr. Payne is quoting from the American catalogues, for, having grown nearly the whole of those mentioned, I regret to say that although there are a few very promising varieties among the 1895 novelties, the majority are not worth growing for further trial. Correctly speaking, they are not all American varieties, several being introductions from Japan *via* California. The catalogue descriptions are very misleading to the English grower. Fisher's Torch is described as producing large blooms, when in reality it is a medium-sized decorative variety, but the colour is very striking.

Miss M. M. Johnson and Radiance were sent as early October-blooming varieties, when with us they are now (December 9) at their best. Miss H. Robinson can hardly be considered an 1895 variety, having been grown in this country the previous season. One of the largest American growers informs me privately that he considers this "the finest, most remarkable and valuable variety" he has. Early in November he cut and disposed of 1000 blooms at 1s. each, wholesale. With us this variety is not a success, neither can it be considered an early variety; the early crown bud, which the American growers "take," with us fails to expand.—W. J. GODFREY, *Exmouth*.

**Coarse Chrysanthemum blooms.**—I quite agree with "H. S." in his remarks on page 443 respecting these, but I am afraid it is useless to attempt to write them down. Nearly all judges profess to object to coarse blooms, but still it is these to which prizes and certificates are awarded, irrespective of colour. In the matter of colour we have much to learn from the Americans; with them it is the first consideration, and flowers are judged in that country for their decorative value only. Can anyone realise what a "beautiful" effect a vase of large blooms of, say, *International*, *Miss Ethel Addison*, or *Mrs. C. W. Clarke* would have? I do not write against large flowers in general; far from it. Bold and handsome blooms should be encouraged, for they show superior culture, but coarse, dull-coloured blooms should not be pointed higher than slightly smaller, brightly-coloured ones. The large, handsome blooms of *Mme. Carnot*, *Mutual Friend*, *Col. Smith*, *Phœbus*, *Wilfrid Marshal*, and others that could be mentioned cannot fail to be admired. I admit there are two varieties which sometimes lose points if lacking in colour, viz., *Vivian Morel* and *Etoile de Lyon*, particularly the latter, but such as *Mrs. W. H. Lees*, *Rose Wynne*, and *International*, which were sent out as coloured varieties, can be shown with success if only of a dull or dirty white. Flowers should be grown for their beauty, and there is very little in the varieties mentioned by "H. S.," excepting, perhaps, *Van den Heede*, and I must differ from "H. S." when he says this is the ugliest of all the coarse flowers. From the late buds the blooms are distinctly pretty, but the colour is not one that shows to advantage in such a building as the *Aquarium*.—W. J. GODFREY.

#### OUTDOOR CHRYSANTHEMUMS.

THOUGH the list of varieties (p. 451) is a fairly good one for giving bloom out of doors, I think a much better selection can be made from more modern raised varieties. Like the indoor sorts, which have been very much improved during the last half-dozen years, the outdoor kinds have undergone a similar improvement. From the middle of September until the same time in November is the season when outdoor Chrysanthemums are valuable. Before that date their blooms are not wanted, so many other hardy subjects being available. After the middle of November we can hardly expect very good returns from open-air plants. Plants growing against south walls bloomed until quite the middle of December. Perhaps during the month of October is the time when outdoor Chrysanthemums are the most valuable, just before the regular indoor sorts are fully developed. In addition to the varieties named by "E. B." (p. 451) the following will give good returns. I do not risk leaving the roots in the open all the winter. When the plants have had their last blooms removed, I have the roots dug up and stored away in a cold frame in refuse potting soil or leaf soil. Here they remain until the middle of February or later. The lights are pulled off every suitable day while they are in the frame to prevent the sucker-like growths becoming drawn up weakly. The roots are then pulled to pieces and planted in boxes in sandy soil, where they make stocky growth, and by the middle of April they are bushy plants. A west border is a favourable site for the summer growth and early autumn

flowering, as in the case of an early frost in October the plants have ample time to thaw before the sun strikes upon them owing to their position. I do not pinch the points out of the shoots, but allow them to grow away freely. *Ryecroft* (*Glory*) heads the list of outdoor varieties; it is one of the most remarkable early Chrysanthemums we have. The colour is a rich yellow, suffused with bronze. It grows 4 feet high and fully a yard through. *Mme. Eulalie Morel* has deep cerise golden shaded blossoms, and is one of the finest of early-flowering Japanese. *Arthur Crepey* is an improved *Mme. Desgrange*; it flowers later too. The flower-stalks are longer, and therefore more valuable for cutting; the colour is primrose-yellow. *Comtesse Fouchier de Cariel* is the best of bronze-coloured varieties. *General Hawkes*, *crimson-amarant*; *Mme. Marie Masse*, *lilac-mauve Japanese*; *M. G. Grunerwald*, *Montagu*, *rich purple-crimson*; *Roi des Précoces*, *crimson*, one of the best of outdoor varieties; *Samuel Barlow*, *bright salmon-pink*; *Vicomtesse d'Avene*, *rose colour*, free and good in every way; and *Mrs. Conway*, *primrose-yellow*, are all good outdoor varieties. E. M.

**Early-flowering Japanese Chrysanthemums.**—Considering the large number of so-called new varieties that have been distributed from time to time, it is remarkable how few are really worth growing. Recently I saw a large field occupied with these for supplying cut flowers for market. Bright and decided colours are sought when one has to grow for sale, but the market guide is also a pretty certain indication of the general taste. In the case of the grower under notice scores of sorts have been tried and found wanting, until one may reduce the popular kinds to less than a dozen. The following are excellent for outdoor flowering, viz., *Mme. C. Desgrange*, white; *G. Wermig*, yellow; *M. G. Grunerwald*, pink; *M. Dupuis*, bronze; *Roi des Précoces*, red; *Comtesse Fouchier de Cariel*, orange-yellow; *Mme. Eulalie Morel*, cerise, shaded yellow; *Mme. Marie Masse*, deep lilac; *Orange Child*, and *Mme. Zephir Liennet*, bronze.—H. S.

**Exhibiting pompon Chrysanthemums.**—The Horticultural Society in Norwich offers prizes for twelve varieties of pompons, six blooms in a bunch, with foliage as grown. As this is much the most effective method of exhibiting this section that I have yet seen, I draw the attention of readers to the class. Usually but three blooms of one variety are required, and, as is very often the case, some of the blooms are quite small, then more of the stand can be seen than ought else. Not so when six blooms of each variety are stipulated for, as the increased number admits of a more pleasing arrangement. So fine an exhibit was the first prize stand, that I give the names of the varieties for the guidance of others. They were *Rubrum perfectum*, rich purple-crimson; *Golden Mme. Marthe*, bright golden yellow; *Marabout*, white, fimbriated florets; *Florence Nightingale*, pale pink; *Comte de Morny*, bright purple; *Ossian*; *Black Douglas*, rich dark crimson; *Mme. Matthe*, white; *Perle des Beautés*, crimson; *Lizzie Holmes*, canary-yellow, tipped rose; *Mlle. Elise Dordan*, soft lilac-pink, and *Eclipse*, bronze-red, tipped yellow.—E. MOLYNEUX.

**Exhibiting Chrysanthemums in baskets or vases.**—The plan of arranging large blooms of Chrysanthemums in baskets or vases to show their decorative effect is, I am pleased to see, much on the increase. Not only does such a method of arrangement dispense with the cups and tubes, but it does away with the uniformity met with in the usual run of exhibitions of this flower. By the aid of some additional greenery, such as *Asparagus plumosus*, *Eulalia japonica*, *Smilax*, sprays of *Berberis aquifolium*, *Cryptomeria japonica*, natural grasses dried, pieces of *Honesty*, or indeed any kind of foliage suitable for the purpose, a few pieces of yellow-tinted *Beech* boughs or sprays of the common *Gueder*

Rose with the bright crimson of its leaves in the autumn are most suitable, especially when care is taken not to place the latter too near blooms of the same colour. At Windsor prizes are annually given for such an exhibit as I have mentioned, and a pleasing feature of the show it makes. Twelve blooms are stipulated for, any section being admissible. The flowers must all be cut with stems not less than 12 inches long. Quality of flower combined with a pleasing style of arrangement is of course the points to aim at. The first prize was awarded this year to a circular basket neatly covered with small-growing Ferns and trails of *Asparagus*, thoroughly hiding the basket. The blooms were excellent and arranged along with *Cyperus alternifolius* lightly disposed. The second prize exhibit consisted of an oval-shaped basket, the wicker-work being neatly hidden with trailing pieces of *Traveller's Joy* and other suitable materials. In both exhibits every bloom could be easily seen. Such exhibits as these illustrate the value of the Japanese over the prim-looking incurved blooms, the stiff, reflexed varieties, and the *Anemone* kinds with their cushion-like centres.—M.

**Chrysanthemum Souvenir de Petite Amie.**—This pure white Japanese is one of the best for decoration. Those who like fairly large blooms, but more of them than are produced by the orthodox method of cultivation, would do well to put in strong cuttings in February, allowing the plants to break naturally and retaining from eight to ten shoots from the first break. This Chrysanthemum is clothed profusely with extra dark green leaves. Mildew does not appear to attack this variety so readily as it does some others.—E. M.

#### SOME MORE NEW CHRYSANTHEMUMS.

SINCE writing the article which appeared in THE GARDEN on page 413 there have been several other meetings of the N.C.S., and a few more varieties have come under my notice which bid fair to become promising kinds. It may therefore be useful to place their names on record.

**SURPASSE AMIRAL** (Calvat).—A very large Japanese variety, having narrow florets of great length; colour golden yellow.

**BONNIE DUNDEE** (Owen).—A well-formed incurved of the old show type; colour golden yellow, tinted bronze, something in the way of *Barbara*, but having flatter and broader florets.

**M. E. ROGER** (Calvat).—The novelty hunter will probably appreciate this most. It is a Japanese incurved, round and solid in build and of good size. The colour is a peculiar pale watery green, on a white ground.

**ROBIN ADAIR** (Owen).—A Japanese *Anemone*, with several rows of long, drooping guard florets. The colour is lilac-blush and the centre is tinted yellow.

**WM. SLOGROVE** (Slogrove).—A large Japanese, rather loose in form, with incurving florets, which are of medium width; colour deep golden yellow.

**OLIVE OCLEE** (Oclee).—Another massive-looking Japanese incurved; the florets are of medium width, deeply grooved, and of great substance; colour golden bronze, tinted purple.

**GOLDEN DART** (Jenkins).—A capital decorative or market variety. A flat-petalled Japanese, pointed at the tips, very free flowering, and of a pure pale yellow colour.

**MRS. HERMANN KLOSS** (Davis).—A Japanese of large size, one of the most distinct and striking novelties of the season. The florets are long and flat, the colour rich golden yellow, suffused crimson.

**SURPRISE** (Jones).—A Japanese *Anemone* of large size; the ray florets are flat and slightly incurved at the tips; colour deep lilac-mauve, centre good and of same colour.

**MME. J. BERNARD** (Calvat).—Japanese incurved, with finely grooved florets, which are very long and pointed at the tips; colour deep rosy lilac-pink, paling off towards the tips to silver.

**MISS PHYLLIS FOWLER** (Fowler).—One of the old type of incurved, very full and deep in build,

medium-sized, pointed florets; colour pale primrose.

J. W. MCHATTIE (Owen).—A large Japanese, very effective; colour rich crimson, with tips of bright gold. Florets of medium width, slightly incurving at the tips.

MRS. R. W. E. MURRAY (Jones).—A very fine globular Japanese, very full and double, deep in build. The florets are narrow and intermingling, and the colour is a pure paper-white.

C. HARMAN-PAYNE.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Snowdrift.**—Amongst reflexed Chrysanthemums this pure white variety occupies a prominent position. The loosely arranged and pointed florets give the blooms a distinct appearance, and, owing to their purity of colour, cannot fail to be admired.

**Chrysanthemum Hairy Wonder.**—Although the varieties of hairy-petalled Chrysanthemums are numerous, there are but very few that are cultivated to any extent. The novelty of this peculiar-looking section appears to have worn off very much. Hairy Wonder is undoubtedly one of the best sorts in cultivation. The perfectly incurving florets fold over neatly, making a really massive bloom, buff in colour.

## BOOKS.

### LES BROMELIACEES.\*

THIS is a handy and well-printed volume of 150 pages, giving a clear account of the Bromeliads, a natural order to which the Pine-apple belongs. Those who may not have seen the collections of species in France or in Belgium, where these plants are far more generally appreciated than in the British Islands, may nevertheless see very full and complete collections of them in the Botanic Gardens at Kew, at Glasnevin, at Cambridge, or at Edinburgh and Glasgow. The Bromeliads have a precision of form, a certain primness of make, and a variety in both their formation and leaf colouring that specially recommend them to our Continental friends, and seeing that their evergreen beauty and variety—in a word, their permanent interest—are so great, the wonder is that they do not more often find a place in our flower markets. Many of the hardier kinds lend themselves to window culture, and on the whole are perhaps even more satisfactory than the commoner species of Aloes, Cacti, Agaves, and other succulents much more often so grown. Like the Cacti, the Bromeliads are essentially South American, where they are often found growing as either lithophytes or as epiphytes on rocks and on trees. One species especially commonly known as Spanish Moss or Old Man's Beard, viz., *Tillandsia usneoides*, is common in the Southern United States, where it drapes the trees in swampy forests all along the Gulf of Mexico, and it also dangles and sways from the Magnolias and Pine trees in Florida and Texas. This kind is of silvery whiteness, and is not unfrequently grown in our hothouses as a curiosity. Its method or mode of fixing itself to twigs and branchlets by its spirally twisted leaves and stems is a very pretty illustration of adaptability to its native environment. Some of the *Tillandsias* were amongst the first of all epiphytes or "air plants" ever cultivated in England, having been brought by sailors from South American ports and hung up in the windows on their arrival at home. One striking peculiarity of many Bromeliads is their inverted bell-shape or vase-like conformation. In some cases the leaves form a water-shed of some considerable area and are broadened out at the base, and are so firmly compressed together below that they form receptacles for the rain or for the heavy dew that is condensed on their leaves during the night. This power or habit of collecting water must be

\* "Les Broméliacées." Par Leon Duval. Bibliothèque d'Horticulture et de Jardinage, avec 46 figures dans les textes. Paris: Octave Doyn, Editeur. 1895-96.

of especial aid towards the full development of these plants in a hot, tropical climate, where the plants themselves exist in open, elevated and sunny positions on exposed rocks and trees. These natural water vessels or receptacles also serve to collect leaves, insects and other débris, so that doubtless some little extra supply of nitrogen, as well as mere moisture, is thus obtained. The flower-spikes of the Bromeliads that thus collect water are by it isolated, and so protected from creeping insects that might otherwise injure or annoy them. These watery receptacles also now and then furnish suitable habitats for other plants belonging to other natural orders, and, apart from various Mosses, Lichens and Schizomycetes, or bacterial fungi, some flowering aquatic, such as the *Utricularias*, have been repeatedly seen growing and flowering in these natural or living fountains. In Costa Rica, and also in Guiana, the lovely *Utricularia Humboldtii*, *U. peltata* and other species have been seen happy and flourishing in the funnel-like sheathing leaves of *Billbergias*, *Tillandsias*, *Lamprococci* and *Echmeas*.

The author tells us that these beautiful plants grow up healthy and happy in Brazilian forests, or high up on the Andes, in the warm parts of Mexico and Peru, in the dense forests of Guiana—everywhere beautiful, growing up or dangling down, bearing flowers like gorgeous butterflies of all colours, green, red, yellow, orange, scarlet or blue. Some have leaves flamed, mottled or striped with red, magenta, yellow, chocolate or purple, and others have curiously flattened flower-spikes like feathers of tropical parquets, or of cockatoos or trogons. One of the most remarkable of all the species is perhaps the gigantic *Puya chilensis*, of which there are paintings in the "North" gallery at Kew (see Nos. 16, 25 and 26 in the Chilean section). Miss North said that to see this one noble plant at home on the cloud-swept *Cordilleras* near Apoquindo was alone worth all the discomforts of a long sea voyage. *Bromelia Penguin* is used in the West Indies as a common hedge plant, and the gorgeous *Billbergia zebrina* is another of Miss North's subjects (see Nos. 31 and 139).

The book contains interesting chapters on the Pine-apple and on its commercial importance to St. Michaels and other islands of the Azores. There is also a chapter on the beauty and usefulness of the variegated Pine-apple plant for decoration, and those already fond of this plant may like to know that there are at least two other variegated forms, viz., *Porteana* and *cochin-chinensis*. Although mention is made of imported fruits, I do not notice any mention of the extensive trade now being carried on in tinned or canned Pine-apples from Singapore. The fruits are pared and the core is scooped out, after which they are covered with hot syrup and hermetically sealed. I also fail to see any allusion to the curious "Hen and Chicken" Pine-apple, which is not unusually met with in the Malay Peninsula, and especially in Labuan. It is simply a proliferous form, having five to seven smaller fruits clustered around the base of the large central one. The Pine-apple is a good example of those American productions which very early in the history of civilisation found their way eastward, back eddies, as it were, in the flowing current of civilisation westward. Maize and Tobacco and, more recently, the now ubiquitous Potato and Tomato are other instances of this reflex action, so to speak, in civilisation.

There are descriptive notices and illustrations, consisting of woodcuts, in the text of all the principal ornate Bromeliads, such as *Tillandsia*, *Billbergia*, *Echmea*, *Vriesia*, *Puya*, *Pitcairnia*, *Guzmania*, *Caraguata*, *Nidularium*, and others less well known, and at the end of the volume are tabular lists of the hybrids, so far as they are known, several being illustrated, and in all known cases their parentage is given. The best collections of Bromeliads, perhaps, on the Continent are those in the Botanic Gardens at Paris, Berlin, Liege, and Leyden. Amongst amateurs, M. le Dr. le Bèle, of Mans, and M. Liais, of Cherbourg, both possess splendid collections, as

also does M. Delavansaye, of Fresnes, Marne-et-Loire. The late Professor Morren was the great historian of the group. His superb collection of living plants, specimens, drawings, and botanical books was dispersed only a few years ago. As I have said, the inflorescences of these plants are sometimes most gorgeous as seen fluttering and waving to and fro amid luxuriant verdure under a tropical sky. At home they live on the trees along with the monkeys, and the toucans and the gorgeous humming-birds hover and flutter around their flowers like so many brilliantly painted fairies on honeyed sweets intent. Orchids and Bromeliads alike are wild and free all around on rock and tree as the tired traveller sips his coffee after his frugal repast, or takes his dessert from the nearest Orange, or snatches a ripe Pine-apple from the hot and dry roadside. In Singapore the first thing the European traveller may see on landing is the cartloads of Pine-apples or of Sugar-cane beside the hot and dusty roads. As a rule a Chinaman is the vendor, and for 3 cents you may pick the finest fruit from the heap, or for 6d. take as many as you can carry. The fruits are so ripe and sugary—nectar oozing out of them, so to speak—that the wily heathen Chinese knows full well that a decently-dressed European will not hug too many.

Home grown Pines are delicious in flavour and in succulence of texture, no doubt, but a Pine ripened in the open air under a tropical sun is finer in all ways. I think Barnes, of Bicton, once ripened Pines in the open air in England by placing or planting them out in a sunny spot after they had become fully formed, and some special comment was made at the time on the additional flavour that had seemingly thus been acquired. We cannot all grow Pine apples, and now-a-days it would not pay to do so, since splendid West Indian fruits of 4 lbs. to 6 lbs. each may be had in London for 2s. to 5s. each; but we can, and I think we ought to grow more of the best of the more ornamental of the Bromeliads than is at present the rule. If only some of our large market growers would take the best kinds in hand, I feel sure they would soon rival the wretched artificial plants now to be seen in some of our public places.

F. W. BURBIDGE.

## STOVE AND GREENHOUSE.

### DAFFODILS FOR FORCING.

AMONG flowers that may be forced into bloom quite early in the new year, and frequently before that time, are both single and double Daffodils. These are, without doubt, among the most popular at this early season; and, unlike some other forced flowers, these Daffodils when properly done lose none of that exceeding beauty that grace their more natural flowering in the open ground in the early spring months. On the contrary, the protection they receive when grown under glass rather adds to their beauty in at least two ways; first, by the purity of the flowers; and secondly, by a considerable addition to the length of their flower-stems. Growers of Daffodils in the open, and particularly in the so-called early districts, know something of the drawbacks from both, and where the flowers are gathered in the bud stage it is a very difficult matter to make the bunches appear at anything like their full worth. With judicious care under glass, however, the flowering stems are generally considerably longer, no mean advantage when required for market. The points in the culture of these flowers calculated to provide this increased length of stem are, firstly, bulbs that are perfectly healthy and of the first size; secondly, it is important that the bulbs should have received a thorough season of rest;

thirdly, that they should be planted by the first week in October, and if a fortnight earlier, so much the better. Other items requiring attention are shallow planting, by which I mean just covering the bulbs with soil; and lastly, their introduction into heat or glass structures preparatory to forcing. I give these points as of importance in their culture, after some experience and observation, and because many in attempting to force Daffodils for the first time are day by day straining every nerve in the direction of having them early in flower, when, as a matter of fact, the very course they are pursuing is in reality opposed to progress. In forcing these flowers it is quite possible to err in planting them too early. Bulbs that have been thoroughly dried and rested start away again into growth very strongly. Such bulbs as these must be made firm in the soil, as the mass of roots descending in a body, frequently lifts the bulb from its place. To avoid risk in this direction it is always best to plunge in 6 inches of coal ashes over all. Bulbs intended for forcing should have been planted at least six weeks previously. From experiments in this direction I have found that bulbs thus treated root, grow, and flower in a perfectly natural and uniform manner. On the other hand, bulbs that have been taken from the soil and potted up almost immediately are by no means so regular and uniform in growth and flower. This is important where pots of such things are grown for decoration and not expressly for cutting, as in the former a display of bloom is the one thing aimed at. Bulbs that have been thus duly prepared may now be introduced into the greenhouse, placing them at first in a quite cool position and away from drying influences.

Where several kinds are being forced, it may form a useful guide to the amateur or beginner if the natural order of their flowering in the open ground be followed. By introducing them into heat in this way much better results follow than by taking them in an indiscriminate way. Of the evil resulting from the latter an instance came under notice a year ago, where such kinds as *Horsfieldi* and *poeticus ornatus* had not only been introduced as the earliest batch, but to make matters worse were placed at once in the hottest end of the house, and quite near the hot water pipes. Despite the heat they refused to move, to the astonishment of the owner of them. To force Daffodils successfully, a moist temperature of 40° or 45° at night is ample, and this should only be very gradually increased as the growth becomes apparent under the early treatment. A cool bottom is always best, and on no account should the pots be placed on open stages with hot-water pipes below. The syringe may be daily used to maintain a moist atmosphere, and as growth advances water may be given freely at the roots. For very early work the Tenby Daffodil (*Narcissus obvallaris*) is the best of the single trumpet kinds, or if healthy bulbs are procurable, *Ard-Righ*. The former, however, is the more popular, of good colour, forces well, and is much cheaper also. As a second early, *Golden Spur* is excellent in every way. Among doubles, the old *Double Yellow* is by far the brightest and noblest of them all, doing grandly as a pot plant, and also making a fine display when cut. The indispensable *N. poeticus ornatus* requires a long season of preparation to force well; first in frames, and from these through one or two stages, each of about a fortnight's duration, with slightly increased temperature each time. If placed from the open direct into heat, the chances are that the flower-stem will become strangled in the

neck of the bulb. Get it to pass this critical spot in the cooler stages if possible, and success is ensured. E. J.

#### TUBEROSES FAILING.

I AM sending some spikes of Tuberoses for your inspection, and shall be glad if you can tell me the cause of their failing. The house in which they are growing is span-roofed, with *Stephanotis* trained on the roof. This has been well pruned to let in the light. The temperature of the house at night ranges from 63° to 65°, according to the weather, with a day temperature of 65° to 70°. The bulbs were potted in the beginning of August in small pots, and plunged in a little bottom-heat to start. The spikes which I am sending for your inspection are from an early batch that have pushed flower-spikes without much leaf growth. I have some 2000 bulbs just pushing their spikes, which have got a good growth. These have been potted from the small pots into 4½-inch pots.—H. LEWIS.

\*\* You appear to have kept your plants at the right temperature both as regards top and bottom-heat, and we do not think the culture is at fault at the start, but from the appearance of the spikes sent we think the top growth has been in advance of the roots. Your second lot of plants now throwing up spikes should do better, as growth should be more active and the pots full of roots. We do not see the advantage of potting twice. Why not pot your bulbs into 4½-inch pots at first, instead of 3-inch pots, and again into 4½-inch pots, as the shifting will perhaps have something to do with the flowers being blind? An excellent plan with bulbs wanted for very early bloom is to plant in the small pots, and allow them to remain in the same pots and in the plunging material till the flowers open. Of course the plants are kept dark at the start, and though a few will push spikes without foliage, there will be few failures if the bulbs remain in the bottom-heat till the flowers show colour.

In your note you say you gave a little bottom-heat to start the bulbs, and at the time you name the season was very hot. Bulbs would require more moisture at such a season, as the African bulbs this season were firmer than usual. Our method is to give one thorough watering when placed in the plunging material, and we found it was not sufficient, as the bulbs made little root growth and too much top. We presume yours is a similar case, and would advise you to give more moisture to plants plunged in a dry, warm border. You do not say whether your bulbs were kept dark at the start, or if you covered over the tops to retain moisture in the soil—a necessity with African Tuberoses. The best way to encourage root growth in advance of the top is to plunge in frames and cover to keep dark, keeping the plants dark till the roots are well round the sides of the pots.

We now come to variety. You do not name the sort you send, but from the specimens received it appears to be the African Tuberoses. We do not like the African Tuberoses, as they are too long in the growth and make weak top growth. By getting late importations of American Pearl, potting late, plunging in fibre or ashes, and growing in the open till October, or with cold frame shelter, the last named will give splendid blooms in November and December. We have seen so many failures with African bulbs that we never advise their culture. They are also so subject to red spider, that it seems impossible to keep them clean, and when the flowers are nearly fully developed they turn yellow and do not open freely. With later bulbs of the African Tuberoses there is more certainty of bloom, but even then they are vastly inferior to the Pearl and others of the American type, which produce dwarf tops, compact spikes, and good flowers.—En.

Plants in J do fibre.—The note on Ferns (p. 117) in this row material was interesting, and

I can in a small measure supplement the remarks made as to its value for plant growing. Hyacinths, Tulips, Crocuses and similar bulbs do grandly in it, and those who find a difficulty in getting loam may rely upon getting splendid results by its use. I am trying other plants in it. Primulas and *Bouvardias* do equally well. Lilliums look most promising at present, and other plants, such as require perfect drainage, should do well. Vines will start in the fibre grandly; indeed, it is an excellent material for striking them, as they soon root into it and are fit to pot on.—G. WYTHES.

#### CYCLAMENS.

"SUBSCRIBER" (p. 452) asks how to have Cyclamens fit for show the first week in November. I can give him details of a case in which this was accomplished to the satisfaction of the exhibitor. The seed was sown in pans during the first week of March; the compost used was very finely sifted, and consisted of one half leaf-mould, the remainder being loam, peat, and sand in equal quantities. Good drainage was given, the crocks being covered with Moss. A pane of glass was laid on each pan, and Moss thinly spread on the glass. The temperature at the time was 65°. The seedlings appeared very shortly, when the glass was removed and the pans placed on a shelf, which was covered with damp Moss and was close to the glass. Directly the seedlings showed the second leaf, and before they were removed from the pans, they were given weak soot water and liquid cow manure alternately with pure water. By the end of April the crocks were as large as Peas, and the plants were placed in 2½-inch pots. One crock was used in each pot, over which a few pieces of rough cow manure were placed, the compost being the same as that used in the seed-pans, with the exception of there being less sand and the soil not being sifted. The pots remained upon the shelf near the glass at the back wall of a three-quarter span house through the whole of the summer, the roof being heavily whitened. The Moss on the shelf was always kept wet, and, the wall being covered with growing Ferns, moisture was continually rising around the young plants. The temperature of the house often ran up to 90° during the summer. In August a repotting took place, this time into 4½-inch pots. In these pots the plants remained throughout the winter in a temperature of 65°, during which time they produced flower-buds, which were picked off as soon as they appeared. Early in June, after being allowed to become somewhat dry at the roots for a period of about three weeks, they were again repotted, this time into 6½-inch size, the soil being merely broken up roughly and the peat omitted. Two inches of drainage were given, over which an inch of rough cow manure was laid. In this case, as in the preceding pottings, the soil was not made firm, but was loose enough for the finger to be inserted into it without difficulty. When potted, the plants were placed in a close frame and kept shaded, more or less, until they had taken good hold of the fresh soil, when air was gradually admitted, the lights being entirely removed before August. The season was a rainy one, and, the plants being saturated with moisture, the only use of the watering can was to supply artificial stimulant. Every bud was carefully picked off until October 1, when the plants were brought into the house, and, after a week in the cool section, were placed in warmth. The foliage, completely covering the pots, was large, handsome, and not drawn; the flowers came up grandly, and at the time of the show, the first week in November, the plants carried between fifty and sixty well-developed blooms apiece, being then twenty months from seed. This is doubtless not express growing, but the results were satisfactory. Frequent smokings were resorted to during the time the plants were in heat to prevent their being attacked by green fly, and had thrips made its appearance, a dipping in a solution of Gishurst compound or other insecticide would have been given. S. W. F.

## LAPAGERIA ROSEA IN THE OPEN AIR.

THE plant from which the spray here illustrated was cut is trained on and covers a north wall 5 feet high by 12 feet in length. A wall 9 feet high at right angles on the west end of the wall covered by the plant shelters it from the west winds. In front at a distance of 18 feet stands a very high vinery, which affords it shelter from the north. On the east side at a short distance are low span-roofed houses, but not sufficiently high to prevent the east winds sweeping along the wall. The soil is composed of equal parts fibrous peat and loam with sufficient brick rubble about the size of Walnuts, and sea sand to keep the soil open. The position is 50 feet above high water mark, and distant 50 yards

less with crimson. Where there are large masses of even these yellow forms they can be wintered without difficulty, but in the case of many of them, and especially the newer kinds, they are generally propagated as rapidly as possible; hence though the plants appear to be vigorous enough, the underground rhizome which enables them to pass through the vicissitudes of winter in a dry state is, in some instances at least, by no means large, and if the plants are dried off, as used to be the case with the old race of Cannas, mischief is sure to ensue. For such I advise allowing the plants to remain in their pots, keeping the soil slightly moist throughout the winter, as so treated many of the plants do not go thoroughly to rest, and there is then no need to draw on the reserve stored up in the underground portion. It is a great mistake, too, to place these Cannas during

may be had nearly the whole year round. In raising them from seed it should be sown by the end of February or early in March, as the plants will then be sufficiently strong to flower well the first season. This flowering race of Cannas is undoubtedly popular at the present day, for a great many of our nurserymen make quite a special feature of them.—H. P.

## TREE CARNATIONS.

I HAVE read with considerable interest all that has lately been written in THE GARDEN concerning these beautiful flowers. It may reasonably be assumed that there is a good deal of difference in the behaviour of these Tree Carnations, directly due either to a different soil

Spray of *Lapageria rosea* from a plant in the open air. Flowers sent by Mr. Nicholson, Bollnede, Conway, N. Wales.

in a straight line from the river Conway. On the 7th of this month there were 130 fully expanded flowers of large size and good colour, and 270 buds in various stages on the plant. It yearly blooms profusely until severe and continued frosts arrive, but occasional light frosts do not injure the flowers.

R. W. NICHOLSON.

Bollnede, Conway, N. Wales.

**Wintering Cannas.**—In the case of the old, strong-growing Cannas which are principally used in the flower garden, but little trouble is needed to keep them in good condition throughout the winter, provided they are kept free from frost and in a fairly dry state, but some of the newer large-flowered kinds are far from particular, especially those whose blossoms are yellow, dotted more or

the winter underneath the stage in the greenhouse or in some such a spot, as they are then liable to get too dry, or to suffer from drip; indeed, an excess of moisture is even more fatal than drought, for in this way the large rhizomes are liable to rot. I have been several times consulted within the last few years concerning the loss among Cannas, particularly of the newer kinds, during the winter, and found in most cases it occurred where the drying off had been carried to too great an extent. At the same time in nearly every instance the mortality was greatest among the varieties with yellow blossoms, whose rhizomes are naturally more slender than those with red flowers. To the amateur with but a single greenhouse these Cannas are very valuable for flowering at different periods throughout the summer and autumn, and where there is greater heat at command their brightly-coloured blossoms

mode of culture, or the locality in which the plants are grown. For instance, as showing what I mean, I may refer briefly to two first-rate

## WHITE KINDS,

Mlle. Carle and La Neige. In this part of Middlesex the former is largely grown by the market men, to the exclusion of almost all other whites, or, strictly speaking, it occupies the leading place for purity, for size, for freedom, and continuity of flowering also. This is by no means the outcome of bigotry, but rather the result of growing side by side all other whites, both new and old. Nor is it arrived at merely by a few dozen plants, but by a comparison of house against house, month after month, and where a living is de-

pendent on the results. The last item is the severest test of all, as the stern necessity of the case will scarcely permit of a good grower of these things being carried away by a beautiful flower only, for beyond this there must be quantity and continued flowering also, or the plant finds but little favour. Then again, as a set-off against this, Mr. Crawford in a recent issue tells us he will not grow Mlle. Carle after this season. Evidently Mr. Crawford grows these beautiful flowers satisfactorily, as witness the editorial foot-note at page 329. Therefore I conclude that soil, locality, or varying modes of culture must be responsible for some of this superiority and inferiority. Mr. Crawford, I notice, also has grown these two whites side by side, and is therefore fully qualified to judge of their respective merits or otherwise. This is exactly as it should be, in the end discarding the less useful variety. Another beautiful and charming white, though (speaking from memory, as I do not grow it now) without fragrance, is Mrs. Moore, but beautiful as it undoubtedly is, it had to be discarded because it was not free enough. When quite new I obtained this and grew it to quite large size, but it was not nearly so free as Mlle. Carle under the same treatment. Then there is that very old and fragrant kind, La Belle, with its strong Clove-like perfume, that many market growers still cling to with a good deal of tenacity. Unfortunately, all the earliest flowers split the calyx, the later ones, with less material, keeping much more intact. Notwithstanding this slight defect, it is largely grown in some districts, including that from which I write. As an autumn flowering kind and up till Christmas it is of especial value, but beyond this time it is not so free till well on into May ensuing. I have frequently counted upon year-old plants of this variety three dozen or more flower-buds, the major portion of which can be secured with 3 inches or 4 inches of stem, and many much longer than this. But La Belle is one of those kinds that require more heat than many, otherwise it comes of a creamy hue and not pure white. In this respect it is difficult to properly treat it in company with the usual run, but with a houseful of plants it is a different matter. I can strongly recommend this old white for autumn use, to be replaced later by Mlle. Carle and La Neige, as the two latter are more strictly perpetual in their flowering. I believe these are all the really pure white kinds worth growing. There is the newer kind Mary Godfrey, but so far as I have seen it is wanting in substance of flower, and decidedly lacking in constitution so far as this district is concerned. The other white kinds, such as Empress of Germany and Catherine Paul, have flowers striped with red, and are certainly not first class. Next to white kinds in importance are the

#### PINK VARIETIES.

These at times are even more valuable than white, though not usually so. Of really pink kinds—I mean the pink of Miss Joliffe—we can readily count them all on the fingers of one hand. The frequent announcements of Miss Joliffe Improved is a snare which every grower of Carnations has fallen into, for in reality there is no such plant in commerce. It is indeed something akin to absurd that Miss Joliffe is rarely mentioned now in Carnation lists, and that everybody's stock has suddenly become "improved." A well-grown flower of Miss Joliffe does not stand in need of this suffix, and in fact cannot be improved, unless the plants are grown a second year, and then the fortunate grower of them will see such flowers that he will never forget. I would like

to suggest this plan to Mr. Crawford, who appears specially fond of Carnations of the perpetual class. I remember quite well seeing and admiring the group of Carnations at Chiswick some years ago when the "improved" was first started. The plants were nothing more nor less than well-grown examples of Miss Joliffe pure and simple, with possibly a little bud-thinning thrown in by way of improvement. I have grown Miss Joliffe more or less for the last fifteen years and handled thousands of plants. A near neighbour used formerly to grow of this kind alone from 10,000 to 13,000, and it was among these that I saw the only "improved" flowers I have ever seen. The plants producing them were two years old, and the improvement consisted in the flowers being nearly twice the usual size, of greater substance of petal, and nearly all the blossoms had triple centres, like we see in some varieties of Roses. These flowers were magnificent, and were grown by Mr. Milne, of Hampton Hill, probably the finest Carnation grower for Covent Garden of the present time and for many years past. Few men are possessed of a fuller, sounder judgment of the merits of a Carnation than the grower I have named. I notice Mr. Godfrey speaks of his pink kind and its value when planted out. I agree with his views of the freedom of this variety for autumn work, but in producing the autumn crop of bloom the plants appear to exhaust themselves very much even when grown in pots, and I think Mr. Godfrey will be greatly disappointed if he hopes that lifted plants are going to flower "right through the winter." Even pot plants of this variety with all their roots intact cannot do so much, simply because plants that produced "sheaves of good bloom in August" must now be devoid of the lateral growth necessary for flowering in winter. Such growth, moreover, from lifted plants is usually only sparsely produced and frequently results in blind buds, particularly in foggy districts. Apart from the kinds named, Mlle. Thérèse Franco is a good and useful addition to the pink shades—in reality a warm rose-pink and the flowers full. I have seen other pink varieties, but as yet these are in private hands. Of

#### SCARLET

varieties there are several good kinds, notably A. Alegatiere, a wonderfully free flowering kind and of good perpetual habit. Lucifer is a rich scarlet and a better flower than the last, but not so free. Winter Cheer has very fine scarlet flowers, that stand erect on good stems. As a flower producing plant, however, it cannot vie with Alegatiere, the latter producing quite double the flowers from plants of the same age. Winter Cheer has a dwarf habit that commends it to growers of pot plants. Other good scarlet kinds I have seen are Foxhunter, Christmas Cheer, Vesuvius, Vulcan, Sir H. Calcraft, W. Robinson and Coronet. Among the

#### CRIMSON SHADES,

Duke of York and Uriah Pike are the best. Of the former I cannot speak from personal knowledge of the plants, and therefore of its winter-flowering qualities I know nothing. Uriah Pike is undoubtedly the finest of all crimsons, a grand Carnation in every way, of good form and powerfully fragrant. This is a true perpetual, yet, while blooming abundantly during summer, autumn and spring, is not a good winter-flowering kind. With a return of bright days, however, it is soon flowering again. Mrs. A. Hensley is also an excellent crimson that must not be omitted. The

#### YELLOW KINDS

among perpetual Carnations are very few, and some good additions to this class would be welcomed. Andalusia has sulphur-yellow flowers, and Pride of Penshurst has clear yellow blossoms. Both are excellent types of Tree Carnations, the latter giving much the best flowers on two-year or three-year-old plants. Like Uriah Pike, this kind flowers best in autumn and very early spring, and during the winter months is best kept quite cool. Intermediate shades are more numerous, but these do not find so many admirers.

These Tree Carnations may be so grown in successive batches as to yield a constant supply of bloom all the year round. Carnations do not grow with the lightning rapidity suggested by Mr. Godfrey's note in a recent issue of THE GARDEN, but by inserting cuttings from October to March at intervals batches that will yield flowers over a long season may be grown in various sizes of pots. The earliest batches may, according to the variety, be stopped once, or the taller kinds twice, if they appear to spike too early. Any cuttings inserted after February are best not stopped at all, particularly so if they are of dwarf habit like Winter Cheer. One point in these plants must always be remembered; it is this: If they are to flower at all well during winter the spike must be pushing up by the end of September. All pinching or stopping should be done with this in view.

E. J.

#### POTTING LILIUMS.

At page 447 "J. C." gives some useful information on this subject. No good grower of Liliams would leave over repotting until the spring. Of course dried roots of *L. auratum* may be purchased in the spring and be potted up. I bought fifty bulbs on one occasion as late as the end of February; they were carefully potted in moderately-sized pots, using the soil in a fairly moist condition. The point I consider of the most importance after potting is the position the plants occupy. The pots should be plunged well over the rims in cocoa-nut fibre refuse, and they must be protected from heavy rains or melting snow. The bulbs have no roots at first (at least, no active rootlets), and a deluge of cold rain might kill half of them and cripple the rest. I always manage to plunge the pots in a cold frame with glass lights, and they are not disturbed until the growth of the plants is seen to push above the cocoa-nut fibre, or whatever plunging material is used. The fibre is then removed down to the rims of the pots, and if the plants are dry at the roots they are watered. This must be done carefully at first, or until it is seen the stem-roots are pushing out freely. This is an important period in the life-history of the Liliam. In the first place, allowance must be made in potting the bulbs. The soil should not be nearer the rims of the pots than 1½ inches, and by the time a good surface dressing is needed it will have sunk to 2 inches. I consider the best potting material for Liliams is two parts good yellow loam, one part fibrous peat and one part well decayed stable manure, with coarse white sand added if necessary. For the surface dressing a double portion of manure should be used. I find *Lilium lancifolium* and the hardier North American Liliams do very well plunged out of doors, without any protection during winter, in districts where I have lived where the annual rainfall does not exceed an average of 24 inches. If Liliams are stood out of doors it is essential that they should be plunged rather deeper. *L. auratum* suffers from being plunged out of doors, although when established in Rhododendron beds or in well-prepared soil it will grow 5 feet or 6 feet high, and in some cases (as in Mr. Wilson's garden at Weybridge) 11 feet. To grow the remarkable specimen alluded to, the bed had been prepared to the depth of about 5 feet. Some Liliams do better planted out than in pots, but they should

not be disturbed too often. I have had *Lilium californicum* doing well for a decade without even surface dressings of any kind, and the noble *L. giganteum* does well in prepared beds of peat and loam out of doors, although it also succeeds when grown in pots. I quite agree with "J. C." as to the importance of potting the bulbs as soon as the old stems decay, and it ought to be done without doing any material injury to the basal roots. The stem roots have done their work and must be removed with the stems. The stems and roots can be removed together by carefully pulling them out by hand.

J. DOUGLAS,  
Ilford, E.

## ORCHARD AND FRUIT GARDEN.

### PEAR MARIE LOUISE D'UCCLE.

THERE are few varieties of Pears more prolific than the above in favourable and unfavourable seasons alike. Amongst a large collection of Pears on a soil far from the best for this fruit, I have not known a failure for many years, there always being a crop, occasionally light, but as a rule very heavy. The tree also possesses

the advantage of succeeding equally well on both the Quince and Pear stocks. In addition to these excellent qualities it may be mentioned that the fruit attains a fair size under ordinary conditions and cultivation, with a good shape and nice russetty yellow colour when ripe. In the large midland markets the fruit realises a very good price in almost all seasons if consigned to salesmen or other purchasers just before it becomes mellow, which is earlier or later according to the seasons. This year all were fit for use by the middle of October, while in some previous seasons the fruit has kept wonderfully well up to the end of November. Market growers who have planted Marie Louise d'Uccle in quantity have had no cause to repent selecting the variety, for though no extraordinary prices are obtained—as is the case with some other varieties—the results are certainly pleasing and practically assured, provided the soil and district will produce decent Pears. On strong and deep land the Quince stock answers splendidly for the variety under notice; in fact, the Pears will be so abundant that heavy thinning is a necessity to get large fruit. When it is seen that the crop is going to be satisfactory, heavy mulching with rich farmyard manure is advisable, spreading it several feet away from the stem on all sides. As a rule, all the finest feeding roots are at some little distance from the trunk, and to pile all the mulching close up to the tree is of comparatively little use, owing to the fertilising elements passing away without touching the fibrous or extreme roots. Another advantage of working Marie Louise d'Uccle on the Quince, according to my experience, is the decided improvement in the flavour of the fruit. Under ordinary conditions its quality can only be classed as fair, and in some seasons even poor, especially from trees on the Pear stock; but, as stated, when grown on the Quince and supplied with a liberal diet at the roots, the fruit acquires a size and flavour that are far superior to those of

many other varieties that lay claim to being good and delicious. A peculiar feature of Marie Louise d'Uccle on the Quince is the way in which the foliage turns up at the sides, as indicated in the illustration. I have about 100 trees in bush form growing on the stock named, and whether the seasons are wet or dry, sunless or otherwise, the leaves close up like a Pea-pod, and this without any signs of bad health or weakness, as proved by the full crops and large fruit. On the Pear stock the foliage seldom acquires the form indicated, or if so, the local influences are different from what they are in this portion of the west of England. Again, seasons have a most wonderful effect on the flavour of the fruit on trees on the Pear stock. Last year the quality was the best I ever tasted; this year it is the worst I ever knew; for although the fruit is well grown, clean, and of high colour, the term "very poor" is the only one applicable. However, in spite of this latter defect, the fruit sold freely at paying prices.

W. G. C.

**Scale on Peach trees**—There are few gardeners who are not troubled more or less with

*Pear Marie Louise d'Uccle. Engraved for THE GARDEN from a photograph sent by Mr. F. Hammett, Sittingbourne.*

this pest, and ordinary insecticides seem of little use in removing it. The paraffin remedy, however, is a perfect one, and if used with judgment quite harmless. Where so many make a mistake is in postponing its use until the buds are too far advanced. They are then easily injured, and fall off as soon as the trees are started. December is quite late enough to apply the petroleum mixture, except in the very latest houses, and care must be taken not to exceed a couple of wineglassfuls to three gallons of warm, soft, soapy water. Apply it vigorously and all scale will disappear.—J. C.

**Best flavoured Pears.**—"D. T. F.," in supplementing Mr. Burrell's remarks on this subject at page 431, objects to Thompson's being placed in the first half dozen for quality. My experience with this Pear is, that it is most fastidious as to soil and climate, and requires a very even season to bring out its finest flavour. I also think Thompson's is more at home in midland gardens than southern ones, as anything like a hurried maturation invariably produces meanness in the fruit. A clayey or retentive soil is also antagonistic to its well-being, the fruit from trees rooting in such a medium usually being cracked and malformed. I used to think that for flavour no variety could possibly equal Doyenné du Comice, but after tasting Hayshe's Prince Consort I unhesitatingly accord it the premier position amongst dessert Pears. From the fact that I have never seen it named in *THE GARDEN*, save by myself, I conclude that it is but little known. This is a great pity, as I am confident that anyone who tasted it would

pronounce it excellent. The fruit is not of the handsomest shape, being somewhat like Burrell Rance, but a little more irregular, green on the under side, and freckled with brown next the sun. It is but right to state that the trees under my charge are growing on a south wall and in a warm soil. The tree is of somewhat slow growth, but an early and regular cropper. December is its usual season of ripening in this district. Probably in southern gardens a west wall would suit it.—J. C.

I quite agree with "D. T. F." (page 431) in his estimate of Thompson's as regards flavour when compared with Marie Louise and Winter Nelis. Thompson's is undoubtedly a useful Pear, but I have for some time past considered the high position given it to be somewhat undeserved. Pears, however, are among the most variable of English fruits in point of quality, and it requires some courage for any grower to express an unfavourable verdict. I feel convinced that the age of my only tree—a large espalier on a west wall—is not the reason for my adverse opinion regarding the flavour of this Pear.—W. S., *Trowbridge*.

### STEWING PEARS.

The stewing Pear is a greatly neglected fruit, although, as Mr. R. Parker so ably points out on page 431, it has a considerable value during the winter season, when the list of English dessert fruits is limited. Why stewing Pears are not more generally grown is somewhat difficult of explanation, for in some, indeed many, private gardens they obtain equal favour with the dessert kinds, and yet, in spite of this, very often there is only a single tree, and sometimes not even this in gardens where choice dessert kinds are appreciated at their proper value. It is quite true that a good many dessert Pears are well suited for stewing and are used for the purpose, but that is no possible excuse for the absence of suitable varieties in too many gardens. In times of a short supply for dessert it is not an easy matter to apportion an equal quantity of good fruits for the two purposes economically. As with the planter, so with judges at exhibitions, stewing Pears do not merit that consideration they deserve; there is usually a loss of a point or two in the decision should a collection contain a dish of these in a close competition. Mr. Parker's suggestion to framers of schedules, where he advises a class for stewing varieties, or stipulates that one dish at least in a collection must be a stewing sort, is an excellent one. This would help to popularise them, and bring them into greater prominence with everyone concerned.

Very large fruits are usually associated with this section, Uvedale's St. Germain and Catillac probably being the varieties to which the most favour has been shown. Medium-sized rather than large fruits I find the most useful, for the simple reason that a far heavier crop is produced by the tree. A few large fruits are very well for special purposes, but in the case of those who are expected to provide an almost daily supply for four or five months, a few large fruits do not avail very much. One of the best Pears I know for stewing is Gilogil, a medium-sized round fruit, and one that may easily be taken for a dessert kind, by reason of its bright russet colour and clear skin. I noticed some fine fruits of this sort in Messrs. Bunyard's nursery last autumn, and, except my own fruit, I do not remember having seen it anywhere else. This, however, does not prove that it is not much grown, but is simply debarré because it does not happen to be a dessert variety of the size and appearance of the much over-rated Pitmaston Duchess. Bezi d'Heri is another variety of much value, this,

too, being of medium or below medium size. With these two a supply can be maintained from September till the end of January. For the last three seasons the latter has not failed to produce a good crop, and the other has taken only a partial rest one out of the three years. This supports the views of Mr. Parker in that these Pears have apparently a stronger constitution and are devoid in a marked degree of the unreliable traits of some of the more popular dessert sorts. Before the planting season closes, I would, with Mr. Parker, strongly advocate the inclusion of at least one tree in a collection, however limited that may be, for there is the chance of having stewing Pears sometimes when ripe fruits are unavailable, except by purchasing perhaps foreign Pears at what to many would-be consumers may be considered a prohibitive price.—W. STRUGNELL.

—Mr. Parker's remarks on these at p. 431 are well worth notice. Some two years ago I advocated in these columns the more extended culture of stewing Pears, and condemned the practice of planting them, as is very generally done, in out-of-the-way corners or behind north walls. How often have we heard the remark by planters that any place will do for stewing Pears. Now I hold that if stewing Pears are worth growing at all they are worth growing well, and indeed pay to do so. Many people are quite ignorant of the difference between fruit, even of the common Catillae, gathered from trees occupying a warm wall compared with those from orchard trees. As Mr. Parker observes, the flavour of a properly prepared dish of stewed Pears is delicious. Then some varieties are far better than others. For instance, Vicar of Winkfield and the more recently introduced Directeur Alphan and are far in advance of Catillac. The former with me is in good seasons sweet enough for dessert from a south wall.—J. CRAWFORD.

#### INARCHING MUSCATS.

I HAVE a number of Gros Colman Vines ten years old. They are planted inside and do fairly well, but I wish to have part of the house Muscats. Do you think Muscats will do if I inarch them on to the Gros Colman? I shall have to purchase young Muscat Vines for the purpose. Should I inarch ripened rods, or cut back and inarch the young growths when strong enough? Would a White Tokay Vine be worth trying in the same house?—JONES.

\* \* You may inarch the Muscat on to Gros Colman stock with every prospect of success, provided care is exercised when the Grapes are ripening. It will be best to inarch young wood on to young wood, but if the Vines are fairly strong and quite healthy, you need not cut them down to the front lights, as this would cause the loss of a crop of Grapes. In order, however, to give the newly-inarched Muscats the best possible chance the first season, cut off all the spurs but one from the Gros Colman for a distance of 5 feet from the first wire of the trellis, retaining one at the base for producing a growth on which to inarch the young Muscats. The remainder of the old rods can then be cropped the first summer, while the 5 feet of Muscat growth trained over the bare portions of the Gros Colman rods will, by having the full benefit of light and air, ripen up thoroughly by the autumn, and thus lay a good foundation for increased vigour the second season.

At the end of the first season's growth the old Vines may be cut back to the point of union with the new, and the young canes have the whole of the room to themselves. If the Gros Colmans are planted, say, 4 feet apart and are strong, then they may remain as they are and be cropped lightly, the Muscats being inarched on a strong shoot at the base of the rod, and be trained up between them, two leaves only being left beyond the Colman bunches to further increase the room and light, the old rods being removed when the young Muscats have reached the top of the house. If

the Gros Colman is at all weakly, the best way will be to cut the Vines right back to the front lights, and to inarch the Muscats on the new breaks when sufficiently advanced. In addition to this the stale soil should be removed from the surface of the border, baring a few of the topmost roots, and laying on from 3 inches to 4 inches of fresh loam, with a sprinkling of bone meal and new horse manure, firming it well. The only objection to having both Gros Colman and Muscats in the same house is that the former is so much later in ripening than the latter and requires much more air while laying on bloom; but if the Vines are started early enough to allow of the fruit of both ripening before the cool, damp nights set in, the same treatment should suit them. White Tokay, although only a second-rate flavoured Grape, is nevertheless very useful when well grown and thoroughly ripened, as it hangs in a firm and sound condition after the Muscats have shrivelled. To ripen White Tokay properly it requires plenty of heat, and the Gros Colman stock should suit it.—J. C.

#### NOTES ON PEARS.

IF "D. T. F." (p. 431) had a thoroughly good Thompson's Pear he would hardly hesitate to include the variety among the best twelve, or, to come even a little closer, the best nine kinds. My experience of this is of comparatively recent date. When planting a stretch of cordons a few years ago I was strongly recommended to give it a trial alike by the firm that supplied the trees and by friends in the midlands and west of England. It has done remarkably well, and that, too, on a soil none too good for Pears—a sandy loam, changing to sand within 18 inches of the surface, and necessitating annual top-dressing to secure good fruit. The only drawback to Winter Nelis is the size; despite taining and top-dressing, the fruit runs very small, not more than two-thirds the size I remember from horizontally-trained trees in an old garden. A good depth of soil, that is at once fairly good and somewhat retentive, is absolutely essential to grow this Pear to perfection. A Pear of medium size that I have (December 8) just finished is Nouvelle Fulvie, a variety that certainly might be included in all lists, as it approaches first-class in quality, whilst the tree as a cordon grows freely and crops well. Personally, I have to put Marie Louise below both Doyenné du Comice and Beurré Superfin from a quality standpoint, for the reason that, whilst I have the two latter varieties as cordons, the Marie Louise comes from old trees with stems 3 feet in circumference that Mr. McIntosh may probably have planted during his stay at Claremont. Other very old trees that I have as yet been unable to replace are Beurré Diel, Glou Moreceau, Vicar of Winkfield, Autumn Bergamot, and Beurré Rance. Beurré Diel from this old tree is only occasionally good—that is, fit for dessert—not more than one season in five; this year is an exception to the rule. Beurré Rance from old trees is a decidedly better late Pear with me than Bergamote d'Espere, which never ripens satisfactorily. To turn from the latest to early Pears, I find Williams' and Clapp's Favourite the most satisfactory; neither Jargonelle nor Doyenné d'Été is of any good, the fruit passing too quickly from the hard to the semi-rotten stage. It might be different if we could transfer them direct from the tree to the dinner-table, but just at the time when the fruit is approaching the ripening stage it has to be sent some 600 miles, and it is difficult to catch it just right. Of Pears lacking in quality, but very juicy and refreshing, and because of their free and consistent cropping qualities often valuable when other varieties are scarce, I may

mention Napoleon and Passe Colmar also from old vertically-trained trees on piers. With respect to all the old trees, the practice adopted of cutting clean away a portion of the projecting spurs each season and laying in young wood along the old branches has certainly given some better fruit, but nothing like so good as that obtainable from healthy young trees. There is a stage when old trees may be re-clothed with healthy wood, but not when they are gone too far; it is then a saving of time and expense to root them out and substitute young trees, especially if there is a large demand for high-class fruit.

Whilst on the subject of Pears, I should like to say a word as to the system advocated in a recent number of THE GARDEN in connection with summer pruning, viz., breaking the shoots partially through and allowing them to hang, a system I remember in vogue in more than one old fruit garden close on forty years ago, as well as the autumn-pruning of Peaches and Nectarines, that also formed the subject of a recent note. The great objection to the hanging shoots always seemed the very untidy appearance. A lot of half-dead shoots and leaves dangling from a wall is hardly in keeping with a trim, orderly garden. Nor is it easy to see where the necessity for the practice comes in if the summer stopping is deferred until the lower portion of the shoot for a few inches from its base is fairly hard; not much after-growth is made then, and the little that one gets is from the two top buds. It may not be out of place at the present time to suggest to those who are about to plant cordons the advisability of making certain not only as to the free-cropping qualities of individual varieties under this treatment, but also their growth on different stocks and on different soils. The cordons planted here, for instance, some five years ago have furnished matter for reflection, the majority going away freely and well; whilst, on the other hand, it seemed impossible to get any healthy growth into three or four varieties, and I have had to replace them. The three worst were Olivier des Serres, Beurré d'Anjou, and B. Bachelier. What is the general experience with these as cordons? E. BURRELL.

Claremont.

**Foreign Apples.**—The other day I saw a couple of barrels that were forwarded as a present, and, being present when opened, had ample opportunity to judge of the condition of the fruit before it was knocked about other than from the packing, and can certify to the fact that the majority had an average of three or four large, deep bruises. The owner cited the familiar saying about "not looking a gift horse in the mouth," and I was tempted to reply with another, as to "what is worth doing at all," &c., and that it would have been far better to have sent one half or even one-third the quantity, and taken measures to ensure their good condition.—E. B. C.

**Pear Winter Nelis.**—No Pear comes up to this, all points considered, for flavour, &c., according to my observation; nor is this conclusion arrived at from a short period. For more than thirty years I have been closely observing the quality, growth, &c., of it in widely different districts and diverse soils. During that time I have never known it to be of bad flavour, and this regardless of situation or soil. I have met with it planted in the open as a bush, on walls on all aspects, and as cordons on a wire beside walks. On an east or west wall I have had the best results, but I prefer west. I have now one on this aspect and one on a south. When in the latter position it needs a lot of water should the season be a dry one. I am aware it is a delicate kind, and some cultivators condemn it on this account. But to succeed with it it must be planted in a warm sandy loam, as in a cold, heavy soil it does not do well.

I find it most advantageous to keep its roots near the surface by mulching. It pays to give it a good supply of manure water when swelling. With me the fruit suffers badly in a very young state if not protected from severe cold, as it causes the skin to harden, and then often the fruits crack when they begin to swell. I protect the trees when in bloom in the spring by placing Fir branches amongst them. Although it has these weak points, I consider this is compensated for by its splendid flavour.—J. CROOK.

**American blight.**—In 1893 young Apple trees, especially cordons, suffered from American blight, and in spite of syringing freely with soluble paraffin, the enemy was not kept under, as one could not use the mixture in sufficient strength to kill all the blight without danger to the new wood and swelling fruit. I have tried various remedies advised during the season: the trees are at rest, but several have failed, doubtless because a portion of the blight is not touched, as in syringing, the portion of tree most affected is often covered by knotty protuberances which shelter the enemy. I tried soot and lime in winter, but it failed. Being determined to get rid of the enemy, I last winter painted every portion of the trees with a mixture of soluble paraffin, clay and fresh lime. It was a long job as large pyramid trees were painted, but the labour was well repaid by the absence of the pest last summer—a season that was most favourable for its development. In painting it is well to use a small portion of fresh lime, as then it adheres more readily to the bark and does not wash off in wet weather. If soluble paraffin is not at hand, it is readily made soluble by working a fair portion of soft soap into the raw paraffin. A pint of raw paraffin will make a gallon of paint mixed with the clay and fresh lime, with a little warm, soft water added after the paraffin is worked into the soap. The grower can ill afford the time to clean fruit trees in the summer with so many things needing attention. By cleaning now more care can be given, well covering every portion of the tree. It is advisable to closely examine new stock and clean it before nailing or staking.—S. H. B.

#### NOTES ON NEW VARIETIES OF APPLES.

Judging by the keen interest taken in any new variety of Apple staged at the leading fruit shows, and the numerous questions asked as to its quality and bearing powers, it would appear there is no falling off in the demand for novelties of sterling merit. There is no question that some valuable additions have been made to our already long list of sorts. According to my experience the following are worthy of a place in every garden, and it is very probable that some of them will prove of value to the commercial grower. While not stating that Royal Jubilee is the best new Apple, it is, in my opinion, in the front rank, and is sure to find favour in the eyes of large and small growers. The fruit is large, of a beautiful golden colour, clear skin, and will keep fresh and sound to the end of March. Really grand fruit of this variety has been staged this year, the finest dish that I have seen having been put up by Mr. J. Watkins, at the November exhibition held at Chester. Probably each fruit weighed over 1 lb. Other advantages are the late flowering and prolific habit of the trees, combined with a sturdy growth, free from canker at present with me; nor can I hear of it being present with any other grower of the variety. Newtown Wonder was awarded a first-class certificate by the R.H.S. in 1887, and it seems extraordinary that such a splendid Apple should not have made greater progress, considering its many good qualities. Trees worked on the Paradise stock bear most freely, even in their infancy, and never fail to produce

a fair crop of large handsome fruit in bad seasons. In good years, like the present one, the crop is very heavy, the same keeping well to the end of May. It is of fair quality for dessert during the spring months, but the fruit is too large for that purpose if other dessert varieties are available. Early Peach will most likely supersede its parent, Irish Peach, for though resembling it exactly in shape, size, and colour of fruit, the tree is much closer in growth, the wood is more freely studded with spurs and fruit-buds, and consequently promises to bear heavier crops. Wealthy is an American variety that promises to succeed much better in this country than most sorts that arrive from that source. The fruit is of good size, model shape, and very handsomely coloured. On our light soil trees worked on the Paradise stock have borne heavy crops each year since the variety was first advertised. White Transparent is not a specially new variety, but it is only recently that its merits have been appreciated at their proper value. After growing this sort for nearly twelve years I can strongly recommend it to anyone requiring a very early and excellent cooking or dessert Apple. With me it is the earliest variety, beating Mr. Gladstone, Beauty of Bath, and others of that class. In ordinary seasons the fruit is ready for use in the third week in July, and is about the size of a well-grown Keswick Codlin, of a beautiful transparent colour, and freely borne on strong, healthy wood. Beauty of Bath is a lovely Apple of a useful dessert size, and finds much favour amongst Apple eaters. At several of our best August shows this variety took all the prizes in the single dish of dessert Apples. Chelmsford Wonder may be termed a failure so far on our soil; trees worked on both the Paradise and free stocks have not produced a fruit yet; the trees are strong and healthy, and they may possibly bear freely later on, as many varieties do not crop in a satisfactory manner until they attain a few years of age; and as this variety was not much known before 1891 or 1892, it is too soon to condemn it. Byford Wonder has on several occasions been referred to in very favourable terms in THE GARDEN during the past two years, and it thoroughly deserves all that has been stated in its praise. Tyler's Kernel is another Apple that, like the preceding, originated in Herefordshire, where there are in the older orchards many varieties not known commercially. Unless I am mistaken, there are some fine old trees around Ledbury of Tyler's Kernel, which was sent out as a new variety a few years ago. According to my experience this sort does not commence to crop very well, even in bush form, until the tree has acquired a fair size, nor does it like severe pruning, the best results being obtained from trees that have had their shoots shortened back very slightly. Lady Sudeley has been before the public for ten years or so, and has become a favourite with growers for home consumption and for market. On our soil this variety bears immense crops of beautiful fruit, and realises a high figure in the market. Gold Medal is a north country Apple of large size, and possesses good cooking qualities, in addition to a prolific habit, but I question if it will ever find much favour as a market variety, as it lacks colour, and the shape is uneven. No doubt there are many other new varieties of sterling value, but I have only mentioned those that I have grown and had some experience with.

Amongst new Apples that I have seen exhibited but not grown, Bow Hill Pippin has struck me as a variety that will occupy a high position

in the future, provided it proves a good bearer and healthy grower, as the fruit is very large, handsome, and firm, and said to be equally good for cooking or dessert. McIndoe's Russet is a likely-looking dessert Apple, of excellent quality. Mr. McIndoe gave me a fruit to taste when staging a collection of Apples, and the flavour was very agreeable; he further added that the Apples kept sound until the end of March. Hambling's Seedling apparently will prove a decided acquisition, as not only is the fruit of the largest size, but it is also of good shape, heavy, and described as a good keeper and free cropper. From several samples received lately I imagine that a few more good varieties will be put on the market ere long, and it is most desirable that planters of Apple trees should reject all the inferior and practically valueless varieties in commerce, and choose only the best and most valuable ones. If there was no demand for these poor varieties, nurserymen would soon cease to keep them in stock.

W. G. C.

#### PEARS ROTTING IN THE CENTRE.

CAN any of your numerous readers explain the following and give a remedy? I have an old garden with some very large, and probably very old, Pear trees (one covering about 520 square feet of wall). The crops are very satisfactory as to quantity, but the fruit has very little flavour and rots in the middle very soon after gathering, the late as well as the early sorts. The garden is in Surrey and the subsoil is chalk.—F. H. LENDERS.

\* \* \* There are possibly several causes that may account for the Pears decaying in the centre in such an unsatisfactory manner. Probably the chief cause arises from the exhaustion of some constituent or element in the soil, as it appears that all varieties are affected in the same way. Very few people are aware of the quantity of plant food absorbed from the soil by large trees that produce even fair crops of fruit, and when one or more of the elements absolutely necessary for the production of good fruit is missing or in too small quantities for the trees' requirements, the fruit suffers in quality, sometimes by prematurely rotting in the centre in the manner of the Pears under notice, or they are gritty or woody in the flesh, with a hard core, and sometimes crack before they are ripe. The composition per 100 parts of the ash of Pears is 54.69 potash, 8.52 soda, 5.22 magnesia, 7.98 lime, 1.96 phosphate of iron, 14.28 phosphoric acid, 5.69 sulphuric acid, 1.49 silica, 0.17 chloride of sodium. According to this analysis it will be at once apparent how greatly potash enters into the formation of the fruit of Pears, and trees that continually bear good crops must be liberally supplied with this valuable manure in some form to maintain the necessary amount in the soil. Some practical men contend that farmyard manure given as a mulch to Pears supplies a perfect plant food, as it contains all the elements requisite to produce good crops of the best quality. This is only correct to some extent, as much depends on how the animals are fed and the way the manure is made and treated afterwards. This I have proved by actual experience. I have employed farmyard manure as a mulch without detecting the least improvement in Pears, simply because most of the valuable fertilising elements had been washed away in the open cattle folds. For that reason it is much better to purchase reliable chemical manures suited to the fruit and the soil. On light soils overlying chalk or sandstone, muriate of potash is a concentrated form that answers

admirably, applying it at the rate of 1 oz. to each square yard as the trees start into growth. If the trees promise to bear a good crop, a similar dressing should be given when the fruit is the size of Hazel nuts, also applying at the same time 2 ozs. of superphosphate of lime, selecting showery weather for the application. This dressing has proved of great service, not only in promoting a fruitful habit, but the Pears have been of excellent quality and always keep well without decaying at the centre so quickly as those not treated as above. Another good dressing for Pears is 3 ozs. of kainit and 1 oz. of bone-meal to each square yard of border immediately the fruit is set. Fish guano at the rate of 2 oz. to the square yard, applying it at the time above advised, acts well on both heavy and light soils. It is always advisable to gently fork or hoe in this chemical or artificial manures at the time of application, and unless the roots are far from the surface it will soon be found that the roots have discovered the food provided for them by forming a perfect network just below the top of the soil; consequently no digging should be done, or these serviceable roots will be injured. At this season sewage, liquid manure, or burned refuse can be given with decided advantage, as each and all encourage fresh root action close to the surface. Root-pruning with large and old trees is a somewhat dangerous practice, and is seldom necessary if the soil is filled with a good diet close to the surface, for, as stated, the roots will quickly find out the stores provided for them, and the effect will make itself felt in the fruit, which will assume a good size, pleasing colour, and extra fine flavour. If the roots are deep down and none to be found within a couple of feet of the surface, it is desirable to remove some of the top soil, adding fresh soil mixed with a little bone-meal, road scrapings, or wood ashes. If peat moss is employed in the stables or cattle sheds, some of that could be mixed with the soil, as I find the roots of both the Quince and Pear stocks delight in this material.—W. G. C.

**Colouring Grapes.**—Whilst "W. L." in his interesting paper on the "Effect of Shade," refers chiefly to the connection of light, or its absence, on wood and leafage, there is one phase of the effect rather of light than of shade I have noticed on the colouring of Grapes. This is usually seen in span houses that run north and south. For instance, I was in October in a span Muscat of Alexandria house on the north side of London where a fine crop of bunches was hanging. But I observed that the berries on the north side were the best coloured, and, remarking upon it, the gardener said that, having seen similar results elsewhere under similar conditions, he believed that this richer colouring of the north side Grapes arose from the fact that some 12 inches or 16 inches of the top of the slope on the south side not being shaded by leafage, the rays of the sun did for some time become fully impinged on the bunches without obstruction, and that it was this excess of light which did the work. On the south side, although the bunches are near the glass, yet there is always a somewhat close shading of leafage interposed between the sun's rays and the bunches, but on the opposite side the bunches get the full force of the sun's rays, for a time at least. I noticed the same thing some two years ago at Fordingbridge in relation to that difficult colouring Grape Gros Colman, and again this past autumn in some extensive vineries at Cobham. Whilst in all the houses, where at the end, side lights gave full access to the sun's rays, the effect was most marked; indeed, the berries were, for a yard or two from these unshaded glass ends, black as Siles literally, whilst all through the centres of the houses they

were poorly coloured. It would be interesting to learn how far this experience coincides with that of Grape growers generally.—A. D.

#### NOVEMBER IN SOUTH DEVON.

THE past month has been the wettest since the memorable October of 1891, when over 10 inches of rain fell, the rainfall having amounted to 7.98 inches against 7.71 inches for November, 1894, and an average of 4.00 inches for the month during the past eighteen years. The number of rainy days was 20, while there were 19 during the corresponding month of 1894. The total rainfall for the 11 months has reached 28.72 inches, a great decrease from the amount recorded during the same period of last year, viz., 41.02 inches, and considerably less than the average, which is 31.64 inches.

There has been but little sunshine during the month, only 47 hours having been registered. The average sunshine for November is 61.40 hours, and the record for the month in 1894 was 73.55 hours. In the 11 months of the present year, however, we are well ahead of the like period in 1894, the record for 1895 being 1792 hours, and that for last year 1529 hours. The mean temperature has been higher than that of November, 1894, and considerably above the average, which is 47.2°, the past month's being 50.3° and that of November, 1894, 49.5°. The highest reading in the screen was 64.1°, which was recorded on the 16th, and the lowest on the Grass 32.0°, which occurred on the 24th.

The month has been especially remarkable for the continuance of strong winds, the total horizontal movement recorded being 9327 miles, which record is in excess of that of any month during the past two years. The greatest movement during 24 hours was 581 miles, which was measured on the 16th, and the greatest hourly, 45 miles, which rate was reached between the hours of 2 and 3 p.m. on the same day. On 17 days the direction of the wind has been from south to west, and on the remaining 13 days from north to east.

In the garden the only entirely satisfactory flower has been the giant Christmas Rose (*Helleborus altifolius*), which reaches the zenith of its beauty towards the end of the month. Strong well-established clumps will throw up fifty flower-spikes 18 inches or more in height, carrying satin-white cups full 4 inches in diameter, shaded on the reverse of the petals with a faint tinge of pink. If the stems are split up for about an inch, the flowers will last fresh in water for a fortnight, and look well arranged with the foliage of *Rhododendron ponticum*, which in colour and form assimilates closely enough to their own leafage to defy any but expert criticism. The variety mentioned lends itself to indoor decoration more readily than any other Christmas Rose on account of its long flower-stalks. Out-door Chrysantheums, with the exception of those growing against walls, where they have obtained a certain amount of protection, have presented a sadly draggled appearance, the ceaseless rainfall not having given them an opportunity of repairing the damage done by the frost of October, which frost, by the way, was very partial, as I have to-day (December 2) seen, not 3 miles distant, a garden where the Dahlias, Geraniums and Paris Daisies have been untouched and are still blooming. *Solanum jasminoides* has held its white flower-clusters through the month, and will, seemingly, not be flowerless until mid-December. I saw the other day in the neighbourhood of Plymouth a fine specimen of *Abutilon vexillarium*. The plant was growing on the outside of a cool fernery and was 8 feet high by 10 feet wide. Although having received absolutely no protection during the last severe winter, it was in rude health, and was still bearing perfect blossoms on its long arching shoots. The blooms are very striking, the bright crimson calyx opening on the lemon-coloured petals, which again disclose the maroon anthers. The foliage is also exceedingly decorative, being for the most part

beautifully marbled, though many of the shoots produce only self coloured leaves. During the present year the plant under notice has bloomed for nearly six months. On November 12 I was given a spike of Polyanthus *Narcissus* which had grown in an open border at Torquay. The truss consisted of seven fully open flowers, their colour being white with saffron nectary. I have never previously noticed such precocity in *N. polyanthus* in England, the earliest date that I have myself picked the flowers being the first week in January. There have been pretty effects from the yellow flowered *Jasminum nudiflorum* straying through the red-berried sprays of *Cotoneaster microphylla*, and late seedlings of the Corn Marigold have here and there in the wild garden given glimpses of the gold of the departed Sun-flowers. On the rockery a few pale blooms of *Gentianella* have feebly simulated the glory of their spring display, and the fast expanding blossoms of the *Laurustinus* warn us of the approach of the new year. The autumnal tints, late in appearance, were fleeting in duration, though for a few days they were exceptionally brilliant. The Elms were bright gold, the Beeches copper-red, while the great Holly trees, with their clusters of scarlet berries, stood out darkly from amongst the gorgeous colouring; but when the pageant was at its height, a south-westerly gale arose, and for a day and a night the air was full of flying leaves, and the gold that erstwhile clothed the boughs soon lay 6 inches deep on the garden paths and lawns. S. W. F.

#### GARDEN FLORA.

##### PLATE 1045.

##### THE HERBACEOUS PHLOX.

(WITH A COLOURED PLATE OF—1, ETNA; 2, GLOIRE D'ORLEANS; 3, ADA LOUISA.\*)

A NOBLE hardy perennial is the herbaceous Phlox in its many varieties, as varied almost as any garden flower in range of colouring and habit of growth. We have yet to see the Phlox well placed in gardens, the stilted, ugly regimental fashion of sticking it in rows in the border or elsewhere not revealing that wealth of colouring that is seen when boldly grouped by itself or associated with things of similar expression.

The coloured plate that accompanies these remarks shows how delightful are the sprays of bloom when gathered from these massive clumps, and how delicate is the colouring of the flowers, the variety Etna revealing a colour brilliant, distinct, and in contrast to the softer hues of the forms grouped with it.

The herbaceous Phlox is divided into two distinct sections. One is the early or summer-flowering, issuing from *P. suffruticosa*, and creating gay masses of bloom during June and July. A suitable selection of these should be made to get colour into the garden as early in the summer as possible, finishing with the taller kinds that have come through hybridising such North American species as *P. paniculata*, *P. decussata* and others. The great point is to get a good selection of varieties. Choose, for instance, those represented in the plate, and if all crude, harsh, unpleasant colours are eradicated, a charming series will remain. In the herbaceous Phlox perhaps more than any other flower there is a surfeit of poor colours—magentas, dingy mauve, unhealthy-looking lilacs, and washy tints that we hope never to see again. Why raisers will persist in offering such colours; we do not know, unless, as is possibly the case, there is a charm to some

\* Drawn for THE GARDEN by Agnes Cook in the R. H. S. Garden, Chiswick. Lithographed and printed by Guillaume Severeyn.

THREE PHLOXES 1 ETHNA 2 GLORIE D ORLEANS 3 ADA LOUISA

people in novelty, whether the variety be an outrage against good taste or not. The varieties shown tell their own tale. Etna is one of the best of all the Phloxes, its flowers rich, decided and well shaped, borne, too, in dense heads, which in the sunshine of a summer or early autumn day are as brilliant as the gaudiest Pelargonium.

Amongst the earlier flowering Phloxes we may mention a few of the best as a guide to those who intend to grow this perennial. A fine white is Avalanche. This is the variety that stands out amongst all others in the large collection of Phloxes in the Chiswick Gardens of the Royal Horticultural Society, and is worth planting to get the effect of the surface of white blossom; it is not tall, but strong in growth and exceptionally free. Purest of All is also a good white, and to go to the other

perennial, and, especially in very hot seasons, suffers greatly if the soil be poor and dry. Phloxes are not averse to moisture, and even when in quite moist places are perfectly happy, although on borders or in beds they succeed well, proving during the summer months among the showiest and finest features in the garden. A good way to propagate is by cuttings to get thoroughly sturdy plants, not relying, as is so often done, upon root-divisions, these being got from old worn-out plants, a mat of growth, the result of years' sojourn in the same spot. If to be divided, take the outer growths, which are strong, and not weak and starved, as those in the centre of the clump.

We hope herbaceous Phloxes will be taken in hand and made to contribute their quota of beauty to the garden in the summer months. They are, in their many lovely gradations

is terminal, and composed of numerous flowers standing from the main axis. The corolla is made up of four petals, the two upper ones of which are erect, and are at least 4 inches long, broad at the apex, but narrowing below to a long slender stalk; the two lower ones are not half the length of the upper ones. The colour is a soft sulphur-yellow. Sir Joseph Hooker compares the inflorescence to a candelabrum, the large yellow petals mentioned above resembling a pair of gas jets. This species was first discovered by Gustav Mann, near the Bagroo River in 1861.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**FRUITING PINES.**—The grower will now be preparing to start a few early plants to fruit in May or early June. To get good fruit at the time named, it is advisable to make a start early in January. Much, of course, depends upon the means at command, plants with abundance of roots and a sturdy growth being required for the purpose named. Those who grow Pines largely often select their best Queens in the autumn and stand them together, having regard to those which are well rooted and with well-balanced leaves, not coarse, thick centres, as often these latter when given more warmth make new leaf growth and fail to fruit freely. Plants with a deficiency of roots or loose at the collar are not good for the above purpose. Where strong plants are needing new surface material or are loose, it is well to give a surface dressing of good loam, to which has been added some bone-meal, well ramming the soil before plunging in the new bed for fruiting. When any large plants have by any means lost their roots, it is well to re-pot, if required to fruit early, giving a smaller pot than the one they have occupied. Remove a few of the lower leaves, and by placing deeper in the pots new roots will form from the stems if the plants are plunged in a brisk bottom-heat. Such plants will form a succession to the earliest fruiters. Plants that have been kept quiet for a time and dry at the roots will need a thorough soaking with tepid water. To get the moisture to permeate the ball, it is advisable to loosen the surface with a pointed stick previous to watering, giving the plants several doses in succession. At the start moisture must be sparingly applied, and drip is most injurious at this season of the year, so that in damping down the weather should be taken into account. The plants will require extra supplies as the days lengthen. The temperature for fruiting plants should be 65° to 70° at night, 5° to 10° higher by day, and in preference to hard firing in severe weather it is advisable to cover the glass outside with some protecting material. I find dressed covers very serviceable for low pits or frames. Very little air will be required during the day, as the warmth from sun-heat through January will stimulate growth. It is well to admit a little fresh air daily about mid-day to sweeten the atmosphere and prevent drip.

**BOTTOM HEAT FOR FRUITING PINES.**—At this season the plants selected for fruiting at the time named require extra care at the roots, and as the warmth is often obtained from manure, leaves or fresh tan, great care is required that the plunging material does not become overheated. The season has been favourable for collecting the materials required. The difficulty with fresh manure is too violent heating, the result being loss of roots. Oak and Beech leaves are the best, and if a good depth can be given there will be a steady and lasting heat. I noted fresh tan, but do not advise it, as one cannot obtain a lasting heat. With leaves the roots are kept in a moist, sweet-growing condition. In making up new beds for fruiters it is well to cleanse the pits before adding the new leaves and to clear out old material that will not generate heat. By removing the old material such pests as woodlice are got rid of, and the drainage can be made perfect. In making new beds solicity

A white Phlox.

extreme we get rich carmine-red colouring in a variety named Magnet, which, like Avalanche, is dwarf in growth. A rather tall kind, the habit of growth quite branching, is Lafayette, the flowers mauve, with a tinge of blush, set off by a rose-coloured eye. It is not poor in colour, as perhaps the description of the shades would suggest. Other good varieties are G. W. Collock, crimson, plant compact in habit; John Anderson, rich rose; John Forbes, rosy pink; Earl of Mar, rich crimson self; Albert Crousse, vermilion; Alice Henderson, delicate rose, and W. Robinson, the best of all herbaceous Phloxes, its colour a delicate salmon-rose tint. One of the best of the delicate lilac-tinted kinds is Eugene Danzanvilliers.

The herbaceous Phlox is not at all difficult to grow if the soil is made fairly rich, well dug, and rotten manure incorporated with it. The planter should remember it is a vigorous

of colour, little known, though familiar in the borders, where they are often shown in a formal, false way.

**Euadenia eminens.**—There are few stove plants which combine to a greater degree than this the qualities of beauty and interest. Whilst it is not one, perhaps, to be recommended to the gardener who has little or no room for plants other than those which will supply cut flowers or serve for room decoration, it is, on the other hand, an exceptionally valuable one where it can be allotted permanent quarters in a tropical house. There are many stove houses throughout the country whose interest would be enhanced by the addition of this and similar things. *Euadenia eminens* is a native of Tropical Africa, and was first introduced and flowered by Mr. Bull, of Chelsea, about fifteen years ago. The leaves are trifoliate and quite smooth, the three divisions being of pointed, oblong shape. The inflorescence

should be the chief point, and if manure is used it should be prepared previously and not used direct from the stables. For fruiterers at this season the aim should be a steady and lasting heat, as shifting causes a check, so that a deep hotbed is necessary. The temperature should not fall below 80°, 5° higher being preferable to excite the plants into growth and form fruit. The plants should be as near the glass as possible, great care being taken in plunging, well ramming round each pot. As the plunging proceeds make as firm as possible to prevent heat escaping.

**SUCCESSION PLANTS.**—These should now be moving steadily, as in their case the drying off will not have been practised. These remarks apply to plants not likely to fruit for some time. Strong plants likely to fruit in July or later will need to be kept cool for a time and drier at the roots. Such kinds as Cayenne and other late sorts will need to be kept quiet, though by this I do not mean that such plants should be kept quite dry. The temperature for these may be quite 10° lower than advised for fruiting plants. Late potted plants of the winter fruiterers will need a liberal bottom-heat, damping down the house in bright weather. Avoid watering overhead, as too much moisture means poor roots and long leaves. Young plants in small pots will need less attention at this season, as being grown in a lower temperature they will not become dry at the roots so readily. Though I do not advise such plants to be kept inactive, it is not well to excite them much, as in a few weeks' time they will make a stronger growth if just kept going now with more warmth at starting later on. If the young stock get their bottom-heat from hot-water pipes, care must be taken they do not get too dry. Suckers on any old stools of winter fruiterers should be kept growing freely on the parent plants for a little time to gain strength. Those taken off at potting time will make good material for next winter.

**FIGS IN POTS.**—This is a good time to start plants for fruiting in May. Some growers start earlier, but get smaller crops in consequence, as the plants often make too much wood if forced very hard. Plants for forcing at this date will have been repotted or top-dressed in the autumn, and will now be ready. A bed of fresh leaves should be prepared and placed in position. A good depth—not less than 3 feet—should be given. The leaves give off a gentle moist heat and soften the buds, causing a free break. For pot plants very little moisture at first will be required if a thorough soaking is given when the trees are placed in the bed. Plants should be kept as near the glass as possible, and the bottom heat should not exceed 80°. A night temperature of 55° to 60°, with 10° higher by day, will be ample, and if the bed should get too hot, it is advisable to loosen the plunging material round the pots for a short time till the heat has sub-sided.

**FIG HOUSES.**—The trees in this house should now be pruned and cleaned if required to fruit early. Cleaning at this season I look upon as most important. I do not know of any fruit tree which breeds insects so soon as the Fig when under glass. Scale during the growing season is difficult to get rid of. One of the best insecticides for the purpose I named at p. 302, when advising the preparation of pot Figs for early forcing, and the same remarks apply with equal force to permanent trees. Much can be done to get the points of the new wood quite clean by using a soft brush, and in the case of the old wood the safest plan is to paint all portions of the trees. Pruning Figs is often left too late. There is no need to delay the work. If deferred, the embryo Figs at the points of the shoots are often swelling. Any root-pruning or top-dressing may now be done. In most cases Figs bear so freely that rich surface-dressings are not required. In pruning it is well to cut away freely to give well-ripened, new wood room to develop, crowding meaning small fruits and rusty foliage. In pruning remove all sucker growths, if any of the latter are not needed to run up for extension.

**GROSS FIG TREES.**—It is not uncommon to see large trees a mass of wood if the roots have unlimited root-run, and now is a good time to take measures to prevent such gross wood. There need be no fear of evil results following root-pruning if the trees are well furnished with good fibrous roots. In cutting gross roots of long standing it is well to keep at a good distance from the stem, to fill in the trench with a compost of loam, coarse mortar rubble, and wood ashes or burnt garden refuse. This will induce short-jointed wood and abundance of fruit. One of the worst sinners as regards grossness is the Negro Largo. If the roots of this Fig can be confined to a small space it is one of our very best kinds.

**KEEPING GRAPES.**—So far the season has been fairly good for late-hanging Grapes. It will be advisable to go over the bunches at least once a week, removing any decaying berries, also dead leaves, as these restrict light and air. During damp weather a free circulation of air will be necessary on the top ventilators, with a little warmth in the hot-water pipes. The temperature should not fall below 45°, and avoid much firing at night to keep up the desired warmth, it being best to have the pipes warm at dusk. The borders, if outside, will need protection to throw off heavy rains or snow, a cheap cover being galvanised corrugated shutters, which are readily fixed, and last many years. Failing these, I have used dry Braeken or boards. Houses in which plants requiring moisture are wintered may with advantage be cleared of the fruit left. These will keep much better in a dry, cool room in bottles.

G. WYTHES.

#### KITCHEN GARDEN.

**COVERING SEAKALE.**—Some gardeners still rely upon the old method of open-air forcing, believing that although a trifle later in reaching a cutting size, the quality is much better. On the latter point I will not differ with them, as doubtless the even temperature which is maintained by the compressed leaves, coupled with the vegetable ammonia rising from them, has the effect of imparting both solidity and flavour. Where, however, it is wanted as early as possible forcing yearling roots indoors must be resorted to. The first batches are not starting into growth so freely and rapidly as usual, this doubtless being the result of the unseasonable heat during September, a time when early planted Seakale ought to be taking on an autumn tint. Rain fell just before the great heat, which made matters worse, and I quite expect old permanent beds will come away more stoutly than usual. Of course, where the latter are depended on for the whole supply, the first lot of stools which have been rested for two years will have been covered some time since, and advantage should be taken of the present open weather to place pots and leaves over a second lot. Should the leaves be wet it will be well to procure more from park or woods in a dry state, afterwards mixing the two in equal quantities, or if compelled to use saturated ones do not tread very firmly, rather waiting a week or two, and after settling, add more to the top of the pots, as wet leaves will if trodden sometimes heat to an injurious extent even if only of moderate depth. Where stable litter has to be used in part, do not exceed the proportion of one-fourth of it to three-fourths of leaves. Thrust a testing stick into the bed as soon as made up, examining it occasionally until the heat has reached its maximum. Any being forced in the Mushroom house should be cut as soon as ready, and if not wanted for immediate use placed in damp Moss in pans in a cool, dark place. Moss is preferable to water for inserting the stems in. If the space is not wanted at once for more roots the old ones may be left for a fortnight longer, as the secondary growth issuing therefrom is always useful for mixed vegetable soups.

**COVERING CELERY.**—In some gardens, where the depth of soil is limited, a sufficiency of it cannot be banked against the rows when earthed up, consequently, should the weather set in wet and

severe frost follow, the Celery is often frozen through, and if a sudden thaw takes place, wholesale decay follows. In such gardens the preparation of protecting material should not be unduly postponed, indeed, the best plan is to cover at once a good length of ridge with Braeken or long litter, allowing it to fall down over the sides. This is most needful with the earlier white varieties, which soon succumb during a combination of wet and frost. As soon as the supply which was laid in the root room in November is nearly exhausted renew it with a few dozen more heads, as it is always advantageous to be able to draw a supply from this source for a time, should a sudden and unexpected fall of snow occur. When trimming Celery for the pantry, take off all the inner portion that surrounds the heart, as none but the actual centre is sent to the dining-room, and the trimmings, if kept back by the man in charge of the vegetable department, may be used in the kitchen for all ordinary purposes, and thus unnecessary raids on the supply be avoided.

**IMPROVING BAD SOILS.**—An open winter always affords opportunity, not only for trenching and ridging all vacant plots, but also for taking in hand portions of the garden which are too strong and retentive of moisture, or are of such a nature that good clean Carrots, Beet or Parsnips cannot be produced in them. Very often the inexperienced make matters worse by bringing to the surface bad soil from the bottom. Where the subsoil is not clay, or approaching to it, this system may be adopted with advantage, but in strict moderation, a few inches only at a time being brought up, so that the frost and wind of an ordinary winter can pulverise and mellow it. This—in March or April, according to the time is ground is wanted—may be broken down and well forked into the ordinary soil, adding thereto at the same time a good percentage of burnt garden refuse, leaf-mould and the sweepings of walks and drives. Where, however, labour can be spared, by far the best method of increasing the depth of the rooting medium in gardens where the subsoil consists of clay is, first of all, to mark out a limited plot and to wheel all the good soil from it on to the adjoining one. Then dig out a foot or more of the inert soil from below, wheeling it into a large heap or heaps, and after forming large mounds by burning up any rough, useless wood which may happen to be on the premises, place thereon, piecemeal, the bad soil referred to, that it may become burnt through and its nature be entirely changed. In due course this may be spread out as thinly as possible, and allowed to lie for a month or six weeks, or, in fact, till sharp frosts occur, finally returning it layer for layer with the original soil to the site from whence it came, adding a good lot of lime or wood ashes, and, finally, trenching the whole, so as to effect a thorough incorporation. No attempt should be made to increase the depth where the subsoil consists of gravel, unless by entirely removing a portion of the latter and carting more fresh soil from a distance. Better by far let a shallow soil remain so—improving it by the addition of enriching materials—than bring up rubbish from beneath and so spoil the whole plot.

**PREPARING ONION GROUND.**—An early preparation of the plot intended for spring Onions is always advisable from a two fold point of view; first, in order to allow of a thorough settlement of the ground by the time the seedlings are rooting freely, and secondly, to avoid treading on the ground in spring, when, after repeated rains, and perhaps snow, it is often in a very sticky condition. To grow heavy crops of Onions the old mode of trenching is not the best, as in this case the manure is buried so deeply that it is a considerable time before the young rootlets reach it; whereas they require support from the very first. The plan I advise is to take out first of all a deep, wide trench at one end of the plot, wheeling the material to the opposite end. Then lay over the whole surface a good thickness of the richest manure procurable—pig manure is unsurpassed for Onion crops—adding a good proportion of soot and wood ashes, then throw the soil forward into the trench piecemeal, well mixing the

above-named ingredients as the work proceeds. By this means an equal mixture is secured from the top to the bottom, and the roots get the benefit of food from their first formation. Unless on clayey soils, I would recommend that the plot be well trodden as soon as digging is completed, as Onions cannot well have too solid a rooting medium, then retreading can take place previous to sowing in February or March. The same preparation may be given to ground intended either for sowing or transplanting Leeks on.

**SEED LIST.**—It is always best to make out seed lists in good time, so that the order may be sent into the seedsman. This is but fair, as the neglect of gardeners in this matter results in overwhelming pressure and much extra work amongst employees in seed warehouses in spring. Moreover, as the general rule is, that the first to come be first served; gardeners certainly stand a better chance of getting satisfaction than when the orders are not sent in till February or March. Taking it for granted that every good gardener keeps a reference, this will make the task of writing out the seed list a comparatively easy one. It is a good way to have a rough plan of the kitchen garden, with the various quarters and borders marked with the crops which grew in them during the past season. One can then see at a glance how to sow so as to give each subject a change of ground, and can, in preparing each plot, add or withhold manure accordingly. Novelties should only be tried in small quantities, more being grown the second year if satisfactory. To occupy much ground with these untried strains of vegetables is unwise, as it often means a falling off in the supply just at the time when it is most needed. Especially is this the case where ground is not over plentiful. J. CRAWFORD.

## KITCHEN GARDEN.

### MUSHROOMS FAILING.

CAN any of your readers inform me as to the reason why Mushrooms on the top shelf of my Mushroom house damp off soon after they appear above ground? The house has a sloping roof and path down the centre, with three shelves on one side and two on the other. It is heated with hot-water pipes and kept at a uniform temperature of 60°. The roof is boarded, felted and slated. Would ventilation be advisable and to what extent?—S. B. P.

\*\* Most probably this failure of Mushrooms to succeed well on the top shelf in "S. B. P.'s" house is due to high temperature coupled, it may be, with heavy daily syringings. After reading "S. B. P.'s" particularly well-framed query, I ought not perhaps to take it for granted that the syringe has been used to excess, but, according to my experience, it is the usual accompaniment of high temperatures, an excess of fire-heat being liable to unduly dry the atmosphere. I have long been of opinion that a temperature ranging from 50° to 55° and the employment of as little fire-heat as possible is most conducive to success, the quality as well as quantity of crop being improved by this lowering of the temperature from 60° or thereabouts. It should be remembered that if the thermometer stands at 60° 3 feet or rather more from the floor, it will be 3° or more higher near the roof. Ventilation would only aggravate the evil, Mushrooms succeeding best in a genial, equable temperature, currents of either cold or dry air checking their growth surprisingly. Mushroom houses ought to be so constructed and sheltered as to quite obviate the necessity for turning on fire-heat other than during the prevalence of severe frosts, and it is not indispensable then unless the supply of Mushrooms must be constant. I have had beds frozen hard, yet these in the following March gave exceptionally heavy crops. At Longleat, Wilts, there is a large and somewhat exposed Mushroom house that those responsible could do nothing with till the sides and roofs were very heavily thatched

with straw and reeds. Thanks to the latter protection, Mushrooms have been a success in this house ever since or for the past fifteen years. It ought to be borne in mind that what obviates the use of fire heat to excess is also calculated to keep down the temperature during the hotter parts of the year, so that it is possible to have good Mushrooms out of a thatched house during nine months in the year. Successional beds formed in these sunny houses will usually keep up the temperature sufficiently high without drying up the atmosphere, and this fact must not be overlooked by those who decide to see what can be done without so much fire-heat. I have had excellent crops of Mushrooms from beds in a house where the syringe was never used, and no water given to the beds till the first crop had been pulled. The manure ought not to be put together till the rank heat has been got rid of by turning and fermentation, beds that over-heat becoming so dry that they cannot be re-moistened. Nor should it be very dry, as the Mushrooms can only be kept going by means of moist, slowly-decaying manure. Sometimes the beds become saturated and cold owing to being softens syringed; at other times the surface is wet and the manure underneath far too dry, the crops failing to reach a serviceable size, turning brown and softening in either case. Mulching the beds with soft, strawy litter serves to keep in the heat and moisture and protects from currents of cold air. In the Longleat Mushroom house wooden shutters fit closely over the beds and prove a good substitute for mulching. In either case no syringing is needed, but the beds should be watered if too dry to produce Mushrooms, or, say, six weeks after spawning (though more often than not this is found unnecessary), and again after a crop has been cleared off, when liquid manure, or water well impregnated with salt (warmed in either case), should be given in sufficient quantities through a rose to well moisten both the surface soil and manure underneath.—W. I.

**Windsor Castle Potato.**—For a main crop, this variety is one of the very best. It is of excellent cooking quality and yields a very heavy crop of fine tubers, that are nearly all of marketable size. During the past season I planted several plots of this variety, some of them quite early, some at what we call the best time, and some quite late, viz., the first week in June, and the last planting gave me the heaviest crop. The reason of these late-planted ones doing so well was that they escaped the severe drought that prevailed up to the latter part of July, and which caused the early planted crops to be somewhat lighter than they otherwise would have been. The late-planted crop grew away rapidly during the showery weather in August, and, thanks to another drought in September, ripened off well. I am now sorting them, and there are really no bad ones. Anyone having to supply a large quantity of first-class cooking Potatoes will do well to curtail the number of ordinary late sorts, and go in more largely for this genuine acquisition to main-crop sorts.—JAMES GROOM, Gosport.

**Brussels Sprouts.**—Like your correspondents G. Wythes and "J. C." (page 415), I am not altogether pleased with the behaviour of the Brussels Sprouts this year, for many of them are extremely leggy, ungainly, and lacking the solidity and firmness of sprout one likes to see and eat. In my case I think it cannot be through planting on soft, newly-dug ground, as the majority are in a quarter which was occupied by early Strawberries until the crop was gathered. The old plants and rubbish were at once cut over with a spade and cleared away, and so hard was the ground that the drills for planting had to be cut (both sides slanting) with a spade, similar to what surface drains on grass are cut. The ground was certainly softer under this crust, but too hard to work with trowels, so handforks had to be used for making the holes to receive the plants, which were good, transplanted stuff with nice balls of roots. I find this was done on June 6, and a thorough soaking of water given—being later

than usual—waiting in hopes of the drought giving way. No farmyard manure was even applied to the previous crop (Strawberries), nor for years, in fact, not since the quarter has formed part of the garden; but artificial manures are freely applied during growth. Too early sowing might to some extent have brought about this state of things, for I sow rather early in boxes in very gentle heat, prick out into cold pits, and harden and plant out carefully. This is my usual custom, and generally the crop is satisfactory, so I fear we have to look elsewhere for the cause. As to the variety Paragon, I am at one with Mr. Wythes, for I also consider it the best in regard to growth and quality, but find the sprouts of Paris Market and Sutton's Dwarf Gem are rather too small on our light, hungry soil. This is not, however, an unpardonable fault in these days of over-large and coarse varieties of strong flavour. The Imported Aigburth and the like I have discarded some years since.—J. R.

**Forcing Asparagus.**—Those who require Asparagus in quantity and are unable to grow their own plants are placed in an awkward position, as, so far as my experience goes, there is great difficulty in purchasing forcing Asparagus worth the name. I admit there is no lack of plants for sale, in fact there are too many. I am aware the growing of Asparagus for forcing is costly, owing to the time occupied by the crop. On the other hand, the price asked is a big one. In my case the results are very poor indeed. I may be told it is owing to hard forcing or other defects, but such is not the case, as home-grown roots are vastly superior, and I shall in future resort to such for early forced material. I purchased more roots than usual, having a greater demand for forced Asparagus in December, and not wishing to destroy a large number of good roots. Others may be more fortunate in having obtained good roots for forcing, but for three seasons roots purchased from various sources have been an utter failure.—S. M.

**Protecting spring Cabbage.**—Now is a good time to go over the quarters where spring Cabbages are growing. My system at this date (the first week in December) is to select a dry day and thoroughly tread the soil on each side of the plants, afterwards moulding up well to the lower leaves, not leaving any portion of the stem exposed, as this is the part soonest injured. The treading, especially in light soil, keeps the plants firm, and also causes a more sturdy growth should mild weather continue. For the past half-dozen winters by following out the above plan I have not lost one plant in a hundred either from frost or running. If the lower leaves can be saved there is a great gain as regards earliness.—G. W.

**Seed Potatoes.**—At this season much can be done to get seed Potatoes ready for planting, as, if allowed to lie in bulk, the strong shoots are lost and the later breaks are more numerous, but less strong. I find it an excellent plan to now select all the tubers for early work and lay in shallow boxes, the small end upwards, placing the tubers close together in the boxes. It often happens that seed boxes or other shallow boxes can be spared for this purpose, and by preparing now valuable time is saved in the spring. The tubers should be freely exposed to light and air after being placed in the trays. The sprouts which form will be strong and much superior in every way to those from tubers in heaps or at all crowded in the store. Of course these remarks also apply to later kinds, but room cannot always be found for them, and it is well to store these very thinly on shelves if boxes are not available.—S. H. B.

**Wireworm in garden.**—This pest is difficult to get rid of in old gardens if measures are not taken at this season to exterminate the pest. I have tried various remedies and find none so effectual as gas-lime. I admit it requires care in its application. Not only for wireworm is the lime efficacious, but for clubbing in the Brassicas there is no better remedy. When the lime is used in large quantities direct from the gasworks it is injurious, but if spread thinly on the surface and

dug in, it is a grand fertiliser. When fresh the lime is very lumpy, and before being dug in it should be finely broken. For land not badly infested, only a slight dressing is needed, but where clubbing is prevalent I have used the lime at the rate of a bushel to the square rod, allowing it to lie for a few days before digging it in. By

me. I do not advise sowing in heat, as the plants do not always take kindly to the soil when planted out. I have found it best to sow in 4½ inch pots early in the year in cold frames just frost-proof, allowing four to six plants in a pot. By the end of February the plants should be set out on a warm border and protected with a little Bracken or cut branches. These will give a fair supply in advance of the plants raised in the open ground in the early spring.—G. WYTHES.

## ORCHIDS.

### PHALÆNOPSIS.

IN my occasional notes on the culture of these beautiful plants throughout the year just closing I have endeavoured to show as plainly as possible the varying treatment required at different times.

It is only by carefully noting the progress of the plants month by month, and altering the temperatures and other cultural details as these become necessary, that the best results can be obtained by beginners. But it must always be remembered that information of this kind must not be taken too literally, and the advice given by an outsider must always be qualified by existing individual circumstances. As an instance, take shading. Plants growing in a steep-pitched, narrow house will be usually found to require more than others of the same species in a flatter and wider structure with a greater atmospheric capacity. The reason for this is obvious. In the latter house more ventilation can be given, the lights being opened wider and kept open longer in the day, a large body of air not being so liable to fluctuations. This being so, the leaves, although at the same distance from the roof glass, will be kept cool until later in the day. I have purposely refrained from giving special times for ventilating, shading, or closing the houses for the same reason, position, aspect, and style of the houses making all the difference in this respect. Another point requiring attention is the way the changes of temperature referred to are brought about.

There must be no sudden rise or fall, but so gradual as to be hardly perceptible, and always corresponding with outside conditions as far as possible. Seasons vary greatly, and although, of course, we do not follow them exactly, yet the climatic conditions have an indirect bearing upon all details of Orchid culture. If this were not so the majority of the exotic species would be resting during the hottest, and therefore driest, months in the year and growing through the winter, the absurdity of which is clear to anyone. There is no need to recapitulate the various points of culture referred to in past notes, such as atmospheric and root moisture, for any thinking person must see that the same argument applies to all, but a short description of some of the better-known and easily grown species may be helpful to anyone making a selection of these magnificent Orchids. The

oldest and perhaps the best known in the genus is

*P. AMABILIS*, a very free-blooming and handsome Orchid. This has thick, lanceolate, deep green leaves, from the axils of which the large branching racemes of flowers spring. These are 3 inches across, the sepals and petals pure white. The lip is three-lobed and very beautiful in structure. The ground colour of this is white, but there are numerous red and yellow spots near the column. The flowers are produced at various times all through the spring and summer, and last a long time in perfection. It is a native of Java, and first flowered in this country in 1838, having been introduced about two years previously.

*P. ESMERALDA* bears much smaller flowers upon an erect spike, these seldom exceeding three-quarters of an inch in diameter. The leaves are small and light green, sparsely spotted with brown. The colour of the flowers is rosy purple, the lip being darker than the sepals and petals. Some varieties are much darker than others. A native of Cochin China.

*P. GRANDIFLORA* is very like *amabilis*, but larger in all its parts and slightly different in colour of the lip. It has been suggested as a variety of *P. amabilis*, but is certainly deserving of specific rank. It was introduced from Borneo in 1847, and is fortunately a cheap and fairly plentiful species.

*P. INTERMEDIA* is rarer. It is a beautiful kind, supposed to be a natural hybrid between *P. amabilis* and *P. rosea*. It resembles the former in habit and the flowers are somewhat similar in shape, but smaller. The sepals and petals are white, the latter with a few rosy purple spots about the base. The lip is three-lobed, the central one crimson, the side lobes purple. This is

*Phalænopsis Schilleriana.*

using lime in moderate quantities at this season the pest is warded off. Old garden soil will greatly benefit by such dressings, as worms, slugs and other pests are got rid of. Soot is a good fertiliser, but does not clear off the pests. For spring dressing soot is excellent.—G. W.

**Failure of Spinach.**—Spinach has fared badly with me, and unless extra measures are taken to provide the spring supply, I fear the return from autumn sowings will be poor. I regret this failure, it being the first for many years. A good breadth of Spinach in March and April, when there are none too many green vegetables, is much appreciated. I notice that Spinach has failed with Mr. Tallack (p. 415) in quite a different part of the country, so I conclude it is pretty general. The September sowing will, I think, pull through; the earlier or what is termed the winter crop will shortly be dug in, as it is past recovery. Doubtless the dry season at sowing time is to blame for the loss of plants. It is not caused by insect pests, as I am most careful to prepare the land for this crop, and in all cases give a new quarter and well dress with soot, wood ashes and lime. I have not seen any good breadths of this vegetable in market gardens. Some may think the failure is owing to the variety, but such is not the case, as I have seen failures from both old and newer kinds. This is the first time the Victoria has failed with

*Phalænopsis amabilis.*

also known as *P. Lobbi*, and is a variable kind, introduced from the Philippines in 1867.

*P. LUDDEMANNIANA* has stiff-looking leaves, about 6 inches in length and dark green. The flowers are 2 inches across, the sepals and petals white, distinctly and prettily marked with brown

and violet-purple. The lip is purple, the central lobe being darker than the side ones. This has been in cultivation since 1867, and is also a native of the Philippine Islands, as is

*P. SCHILLERIANA*, the most easily cultivated of all and a lovely species, the leaves being very handsomely marked. The flower-spikes are long and much-branched, the individual blooms being from 2 inches to 3½ inches in diameter. The sepals and petals are light rose, shading to white at the margin, the lip three-lobed, the central lobe lighter than the side ones and having a yellow centre and many bright red spots.

*P. STUARTIANA* somewhat resembles the last-named in growth, but the markings on the foliage are not so constant. The flowers are each 2 inches across, the sepals being creamy white, spotted with red at the base, the upper portion pure white. The petals and also the lip are white, the latter being spotted with red. A native of the Philippines, introduced in 1881.

*Dendrobium chrysanthum*.—It is rather late for this to be in bloom, but I recently noticed a fine piece, profusely flowered, in a group of plants at a local show. This plant, unfortunately, was tied up to stakes placed in the pot, so that the natural pendulous habit could not be seen. This greatly mars the beauty of the pendulous kinds, nor do they thrive so well when tied as when growing naturally. The worst fault of *D. chrysanthum* is the evanescent character of the flowers, for they are bright and effective in colouring and have the additional advantage of being sweetly scented.—H. R.

*Celogyne barbata*.—If we except the well-known *C. cristata* this can hardly be styled a popular genus, although it contains many fine garden Orchids. *C. barbata* is one of these—a robust, healthy-growing species, constant in flowering and by no means devoid of beauty. The blossoms are produced on erect scapes, each bearing about six or eight flowers, which are each upwards of 2 inches across and of good substance. The petals, sepals and lip are all pure white, the latter being ornamented with a crest of reddish brown hairs, giving it a very distinct appearance. *C. barbata* may be grown either in the cool house or with the Cattleyas in a good light, but screened from bright sunshining. The compost best suited to its requirements is equal parts of peat, Sphagnum Moss and partly decayed leaf-mould, using with this plenty of crocks and charcoal to ensure aeration. The plants should be potted soon after flowering, not disturbing the roots more than can be avoided. When established in the new pots and all through the growing season plenty of water will be needed, and the atmosphere also must be well charged with moisture, but after the growth is finished much less will suffice. It is a native of Northern India, introduced in 1837.

*Odontoglossum gloriosum*.—Although many of the varieties of this species are weedy and ineffective in colour, some are really fine Orchids, but the best of them cannot be described as first-class. It is often imported for *O. crispum*, but is of course perfectly distinct. A pretty type I noted recently was of the palest creamy yellow, the many spots having a purplish tint in place of the usual dull brownish-red, the contrast being very effective, not only on account of its freedom of blooming and easy culture, but also the pleasant perfume of the flowers. This deserves a place in all collections. It does well under the coolest treatment and likes plenty of water all the year round.—R.

*Brassavola glauca*.—Well flowered plants of this Orchid are very attractive, the pure white lip being the showiest part of the flower, which is produced from the apex of the current year's growth after the manner of a Cattleya *Triane*. It is a species that delights in a strong moist heat provided there is a good circulation of air, and the plants need only be screened from the brightest sunshine. It may be grown in baskets or in pots and must only have a thin surfacing of compost made up of the best peat fibre and

Sphagnum in the proportion of two of the latter to one of peat. Some rough lumps of charcoal may be mixed with this, and in potting or basketing the plants the material must be made firm about the roots. Plenty of water must be given while the growth is active, and though this must be decreased when at rest, at no time must the plants be really dry at the root.

*Odontoglossum Humeanum*.—This pretty Orchid is now in flower, the spikes being much earlier than usual. A plant with about ten bulbs has produced three spikes, thus showing its free-flowering nature, as two only are leads. The plant thrives well with the other species. The flowers are like those of a good form of *O. Rossi* in shape, the sepals lemon-yellow, and the petals white, variously blotched with brown. It is a rather uncommon plant and is supposed to be of hybrid origin, the suggested parents being *O. Rossi* and *O. cordatum*.

*Odontoglossum Edwardi*.—This plant is now in bloom, the number of flowers being over eighty. Each blossom measures about an inch across, the sepals and petals being violet-purple, the lip similar, with a prominent yellow crest. *O. Edwardi* is a free-growing, vigorous species from Ecuador, whence it was introduced about fifteen years ago. The best place for it is a light position in the cool house, closely shaded during the summer, but in winter it should have a temperature of about 55°, as the flowers do not open well in quite a cool house. The compost for this kind may with advantage be used in rather a rougher condition than that for *O. crispum* and its allies. The pots, too, may be rather larger in comparison with the size of the plants. Its growing season should be from the new year onwards until late in the autumn, but it is rather an erratic species in this respect, the plant referred to above not having made a move for nearly three years, but it is now showing a strong and vigorous new shoot. A peculiarity of *O. Edwardi* is that some plants produce flowers that are sweetly scented, while others are quite odourless. It is perfectly distinct from all other *Odontoglossums*, and its colour is not usual in any genus of Orchids.

#### NOTES ON CATTLEYAS.

By far the greater number of this popular genus are easily cultivated—that is to say, there is nothing particularly difficult as long as they are kept to their proper routine of growth. But unremitting attention they must have if the cultivator is to be successful, for, unlike many Orchids, they are extremely difficult to bring round if they get into an unhealthy condition. Bearing this in mind, careful growers watch their plants narrowly and always endeavour to anticipate their wants, and by these means keep them healthy. At this season the growth of most of the plants is at its lowest ebb, very few of the better-known kinds making any growth during the winter. But it does not follow that therefore they need nothing done to them; on the contrary, there is usually plenty of work to be found amongst them. Cleaning is of course a perennial trouble, and must be pushed on with every opportunity, for although the plants look clean, there are often insects lurking about them unseen. It is a good time now to look over the plants and renew the stakes where necessary, and a little more care than is generally taken with this part of their culture would be well repaid by the improved appearance of the plant. Small and medium-sized specimens, or, say, those in pots up to about 6 inches across, should have a strong, but neat stake in as near the centre of each as it is possible to get it, and the pseudo-bulbs may be looped up to this, disposing them as regularly as may be. The raffia or bast used for tying should be twisted up tightly in the fingers, as it looks much neater and stands a greater strain than if used flat. Tie it as low down the stake as may be, and cut off the top of the latter so that it does not show above the top of the plant. Larger specimens will require more stakes, which must be inserted care-

fully between the roots, and a thin strand of matting should be passed around the pseudo-bulbs with a running knot to each, thus securing them in any position required. Plants only partly established of course require greater care in tying, as, not having many roots, there is nothing but the stakes to steady the pseudo-bulbs. Among those advancing into flower are *C. Triane*, *C. Percivaliana*, *C. amethystoglossa*, *C. chocoensis*, *C. Skinneri* and a few others, and these may be placed in the sunniest position. They will not require much water at the root as yet, but as soon as the buds break through the sheath, the supply may with advantage be slightly increased. It is very important that when the plants are watered, enough be given to soak the whole of the contents of the pot, as this lasts for some time and prevents wetting the base of the pseudo-bulbs so often. After the turn of the year more damping will have to be resorted to between the pots, especially should severe weather render the use of more fire-heat necessary.

*Mesospinidium sanguineum*.—The elegant drooping racemes of this pretty little Orchid make a welcome bit of colour in the cool house, the soft rosy tint and the fleshy appearance of the flowers being very distinct and attractive. In habit this species resembles *Oncidium ornithorrhynchum*, but is smaller in all its parts. Newly-imported plants should be grown for the first season in the Cattleya house, as the pseudo-bulbs are always larger than if grown in the cool house. Afterwards the cool house suits it best, as the plants soon get overrun with insects if grown in much heat. They may be placed in baskets or small suspended pans, or they will thrive equally well in pots, but in the former the pendent spikes are shown to better advantage. Not much material is required about the roots, as these are not very vigorous; therefore the receptacles for them must only be large enough to take the plants easily. Good peat fibre and Sphagnum Moss in equal proportions, with enough crocks or charcoal to ensure porosity, will be a suitable compost, and this must be firmly bedded about the roots. Plenty of moisture is needed both at the roots and in the atmosphere, and as the plants are subject to the attacks of thrips, frequent dewings overhead are beneficial during hot sunny weather.

*Oncidium crispum*.—This species is a native of the Organ Mountains in Brazil, and was introduced into Europe as long ago as 1830. In spite of the many later introductions, it still remains one of the very best of autumn-flowering Orchids. There are at the present time several large specimens finely in bloom in the Orchid house at Kew. Some of the pseudo-bulbs are 4 inches high and 2½ inches across, the flattened sides being curiously ribbed. Each of the newer ones is surmounted by a pair of leaves, the largest of which are 10 inches to 15 inches long, very stiff in texture, and of a deep olive green. The flower-spikes are 2 feet to 2½ feet high, branching, and bearing from twenty to forty flowers. The flower is 2½ inches across, and chiefly of a rich reddish brown; a patch of yellow occurs on the centre of the lip and a thin marginal line of yellow also runs round each sepal and petal. Many of the *Oncidiums* are rather difficult to keep in health for long after importation. Fortunately *O. crispum* is not one of these, but, on the other hand, it is one of the most amenable to cultivation. It does not require any very large amount of compost to root in, and may very well be grown on Teak rafts or in shallow baskets. It enjoys an intermediate temperature and should always be kept moist, more especially so, of course, when in active growth. It likes plenty of light, and may consequently be conveniently grown along with the Cattleyas.—P.

**Colour in bark.**—At this season of the year anything which gives colour in gardens, whether as shrubs or trees, is very welcome. Some of the Willow family have very bright yellow growths, and were obtained from hard cut-back stems

or shoots in bunches they are very pleasing. One of the reddest-wooded of the family is *Salix vitellina Britzensis*, which just now furnishes a bright, pleasing contrast to the yellow-wooded forms. I saw this the other day at Cocombe Wood, and, more striking still, perhaps, the reddest-stemmed of all shrubs, *Cornus atrosanguinea*. The plants had been hard cut back the previous spring, and had thrown up shoots some 3 feet long, almost blood-red in colour. This, grown and treated as a compact shrub to produce clusters of growths in this way for winter colouring, would be effective indeed. No doubt there are many other hardy shrubs that might be similarly treated to secure like effects.—A. D.

## FLOWER GARDEN.

### EPIMEDIUM LEAVES FOR CUTTING.

AMONG the many interesting and beautiful plants to be found in the outdoor garden during the winter months, fine healthy masses of *Epimedium* are sure to attract attention. Here we have a plant bold and graceful in its leaf growth, and not only hardy, but retaining its leaves with such persistency that they only begin to die away when another crop has arisen to replace them. It is a precious plant, capable of good use in association with other hardy winter evergreen perennials, as the *Megaseas*, *Hellebores*, *Yuccas*, *Heucheras*, and the many *Rockfoils* and *Stonecrops*, all lovely in colour. Not only in the outdoor garden, but inside as well, the leaves of the *Epimediums* will be found useful to arrange with flowers and spare the tenderer leafage. Though the frost may have been very severe, one will not visit the *Epimedium* tufts in vain to secure such leaves as those shown in the accompanying illustration, which so admirably portrays their outline and airy elegance poised upon thread-like stalks. The leaves generally are of a deep bronzy-green colour, but if a few plants are grown in a sunny spot at the foot of a wall or fence, they will take on delightful hues in autumn and retain them through the winter with all the leaf veins prominently delineated in deep bronze on a lighter ground. *Epimedium alpinum* and *E. pinnatum* are easily grown in any soil, and are pretty spring-flowering plants, but we should know them better and prize them more for their persistent leaf beauty, and use the leaves frequently, too, in floral arrangements. Old-established tufts throw up masses of leaves quite 2 feet high and the same in diameter. Established roots of the *Epimediums* make excellent subjects for forcing into flower in March and April. The plants should be kept in a cold frame until the end of January, when they may be placed in an intermediate house and stood on a shelf near the glass. If kept well supplied with water, the plants will come into bloom and the flowers will be found very useful for cutting.

### A GARDEN OF HARDY FLOWERS.

IN a garden of hardy plants there is ever springing into blossom some momentarily forgotten plant rendered all the more welcome because forgotten for the time. And so on, from the earliest spring-time till far away into the waning months of the year is there something interesting. Such a garden is a constant source of enjoyment as well as a veritable store-house of surprises, and its possessor is never without an abundant supply of flowers. All these facts have for years been known to Mrs. Fitzwygram, who has just such a garden of hardy flowers at her residence at Larkfield, Hampton Hill. It is by no means an elaborate garden, rather the reverse,

where one finds a variety of beds and borders, all of simple design, filled to overflowing with choice hardy plants and bulbs. In size it is between one and two acres, and of this a portion is set apart for the growth of vegetables and the like, while the largest portion is reserved for the flower garden. For the most part the flower-beds are situated on the margin of the lawn, these being carefully separated one from the other by evergreen or flowering shrubs or trees. Very early in the year may be seen masses of colour in the *Aubrietias*, *Arabis*, and *Forget-me-not*, which are used in plenty for the margins, and later on in almost every available nook large masses of fragrant Pinks. The earlier bulbs, such as *Crocuses* and *Snowdrops*, are of course not forgotten, and may be seen in plenty fringing the shrubberies and similar places. Again, in grassy spots, quietly nestling at the foot of some tree or other such things, springs up year by year the winter *Aconite*, bearing them company. Much is made,

Space will not permit of the almost endless array of perennials that occupy the beds and borders, but among the most prominent are *Iris*s, stately *Delphiniums*, *Coreopsis* and *Phloxes* of the herbaceous section as well as those of alpine habit. Many of the choicer *Campanulas*, such as *grandis*, *carpathica alba*, *persicifolia alba* (the last a capital plant and very useful, always creating a fine effect by the purity of its blossoms), *Eucomis punctata*, *Montbretias*, large established masses of the *Alstroemerias* (which are very effective year by year and are never disturbed), *Gaillardias*, the *Japan Anemones*, *Michaelmas Daisies*, perennial *Sunflowers* in variety and such-like receive every encouragement. In the shrubbery are clumps of *Polygonum cuspidatum*, *Boceonia cordata* and similar things, while arches and festoons of *Roses* abound. Especially vigorous and successful are some of the climbing *Roses*, the variety *Mme. Berard* in particular being exceptionally strong, some of the leading shoots of this variety being

Foliage of *Epimedium pinnatum* in a bowl. Engraved for THE GARDEN from a photograph by Mr. J. C. Smith, Nandana, Penrith.

too, in this garden of simple fragrant flowers, such as *Stocks*, *Sweet Williams*, *Primroses*, and *Polyanthuses*, and of the last a capital strain exists, notable for their vigour as well as their rich and varied colours and bold trusses. There is such a wealth of beauty in these flowers, that one wonders why they are not extensively employed in spring gardening, either alone or in company with some of the taller *Tulips* in masses of given colours. A somewhat exceptional experience in this garden is the great variety of *Apple blossom* in the shrubberies in spring-time. Originally planted with *Poplars* and other trees that sent their roots far and wide, robbing the soil as well as the flowers of the light and moisture they so much needed, their places are filled with the *Apple trees*, which in turn are both beautiful and useful. *Apple trees* are also planted here and there on the lawn, but only on the margin and at the furthest extremity. It is certain that a very pretty effect is produced here by their association with other things in the shrubbery.

more than an inch in diameter. A covered archway of this *Rose* has been quite a feature, with a rich profusion of its beautiful blossoms over a long season. There are many other *Roses* in this garden grown either as bushes or standards, many of the *Hybrid Teas* finding a congenial home in sheltered spots away from cutting winds and the like. As may naturally be expected, *Carnations* are especially valued, particularly the selfs and the more fragrant kinds. Apart from an assortment of border kinds, a strain of seedlings of Italian origin, I believe, has bloomed profusely all through the season, and quite late in September was still yielding many useful flowers.

Among useful climbing plants *Clematises* may be mentioned as well as the *Everlasting Peas* (*Lathyrus latifolius*), while the *Sweet Peas* and *Canary Creeper* are employed wherever a suitable opening offers. Quite 7 feet high and brilliant with blossom was a large hedgerow of *Tropaeolum tuberosum*.

E. J.

## NOTES ON HARDY PLANTS.

**Gaultheria procumbens** is a December rock garden plant beyond all praise, dwarf, bright, the evergreen foliage richly tinted with warm red-brown; berries big and brilliant, interspersed, as they are nearly the year round, with some of the pretty bell-shaped flowers of a soft flesh-white. We have indeed a maximum of good features in a creeper of whatever period, but all the more valuable in December, continuing in evidence all the winter. The plant can take care of itself in any peaty soil, but to have it do well it should have good living. This may be given in the form of an annual much of rotten leaf-mould and a little silver sand, and if a pinch of Peruvian guano is added all the better.

**Vaccinium Vitis Idæa.**—This is a capital companion to the above. The Box-like foliage at this time assumes a desirable bronzy hue and the bright scarlet berries are exceedingly pretty, but you only get a good show of the fruit on plants well cultivated, I think; anyhow that is my experience. The plant is rarely taller than 9 inches. Used as a rock plant it should have some vegetable soil and a moist position. I do not think there is much to be said for the name majus as applied to a supposed variety. I grew it and believed in both the plant and the name for a while, but, growing the type and it side by side, they became indistinguishable from one another. With good culture the type soon increases in size in all its parts except stature, the fruit especially becoming large, quite the size of ordinary Kentish *Invicta* Pea.

**Polygala Chamæbuxus purpurea.**—To complete a trio of evergreen creepers for winter effect in the rock garden I would add this to the foregoing. Just now its pale apple-green leaves are crowded with buds in all stages of development, and a few flowers are open, others come forward when there are a few fine days all through the winter, just as do the Periwinkles. This creeper seems fond of a marly loam if the position is moist, and it is a fact not, I believe, generally known that this purple-flowered form is much more robust in constitution and free flowering.

**Ranunculus Macauleyi.**—This is a small plant with big flowers, and, though a native of a warmer clime than ours, has proved at least hardy enough for a winter like 1894-95. Of course, its habitat must be a cold one at 1000 feet to 4000 feet. My experience of it is that it does not rest so completely in winter as we like to see all herbaceous alpine, the young leaves suffering from late autumn to spring. It flowers at a height of 6 inches to 8 inches in gardens. The golden cups are of a rich orange tint and distinctly veined; they can be just covered by a florin, and are sparsely produced in upright, stout stems. Generally in its somewhat glaucous foliage and habit it resembles *R. amplexicaulis*. The roots, too, are of the same order, stringy, and radiating from a well-defined crown.

Woodville, Kirkstall.

J. WOOD.

## COLOURS IN FLOWERS.

AT pages 371 and 420 some instances are given of genera which produce both yellow and blue flowers. I cannot admit that the Pansy is ever really blue enough to come into the category. I can, however, add another—*Salvia glutinosa*, a distinct, though a pale yellow.—WM. WICKHAM.

— In addition to the instances mentioned on p. 450, blue and yellow forms occur in the following families. I may remark that the blue in *Polyanthus* is not good; the yellows are good enough. We must go to the *Primula* species for good blues. *Anemone*, *Clematis*, *Astragalus*, *Gilia*, *Lathyrus*, *Hyacinth*, *Aconitum*, *Baptisia*, *Brodiaea*, *Delphinium*, *Billbergia*, *Verbena*, *Sisyrinchium*, *Scutellaria*, *Tropeolum*, *Statice*, *Tenarium*, *Tillandsia*, *Nymphaea*, *Mycotis*, *Oxytropis*, *Pentstemon*, *Vicia*, *Trichonema*, *Salvia*, *Polemonium*, *Campánula*, *Allium*, *Meconopsis*, *IXIA*, *Gentiana*, *Asteroccephalus*, *Lithospermum*, *Moræa*, *Jacaranda*, *Muscari*, *Ceanothus*, *Crocus*, *Convolvulus*,

*Ipomæa*, *Iris*, and if you admit *Linosyris*, in *Aster* also. I have no doubt in many others.—T. SMITH.

— A little search would reveal many more families of plants with both yellow and blue flowers. Here are a few that occur circa: *Crocus*, *Hyacinth*, *Delphinium*, *Clematis*, *Polemonium*, *Muscari*, *Meconopsis*, *Iris*, *Anemone*, *Allium*, *Linum*, *Ipomæa*, *Sedum*, *Gentiana*, and I have no doubt many others.—T. J. W., *Crouch End*.

— The scientific committee of the Royal Horticultural Society are desirous of carrying out some experiments upon the effects of ingredients in the soil upon the colours of flowers. The secretary will be glad to receive any information about accidental or other results which florists or other cultivators have met with. Any references to published accounts of changes of colours in flowers will be thankfully received by Rev. G. HENSLOW, *Drayton House, Ealing*.

## MARKET GARDEN NOTES.

**FREESIAS.**—The only way in which these can be made to yield a profitable return is to get them into bloom as early as possible, anticipating the large supplies of this flower from the Scilly Isles. These come to hand so early in the spring, that fair prices for *Freeseias* cannot be relied on after February. By a proper system of culture one may have the plants well in bloom in December and January, and at that time the returns are sufficiently high to admit of a fair profit. It is not so easy to procure such an early bloom from imported bulbs as from those that have been forced for a couple of seasons. The earlier the bulbs start into growth the sooner will they go to rest. In an ordinary way the foliage dies off early in July, and the bulbs require at least a month's rest before they are repotted; whereas, for blooming at the close of the year they ought to be growing freely by the middle of August, so that they are throwing up their flower-spikes by the end of November. In a constant temperature of from 50° to 60° they will come into bloom by the close of December.

**DAFFODILS.**—It is with these as with *Freeseias*: they must be in the market before the earliest supplies from the Scilly Isles reach us. For early work, *obvallaris* is one of the best; it forces well, is naturally very early, and being so firm in texture, does not suffer in travelling. Unfortunately, being one of those *Daffodils* that do not thrive and increase freely in many soils, it is dearer than the old double and princeps, both of which are admirable market varieties, force well and can be bought at very cheap rates. *Spurius* is a good market kind, one of the very earliest *Daffodils*, but not so bold in appearance as princeps. A high temperature must never be applied to *Daffodils*, but only enough warmth to keep them gently moving. For early supplies, about 1s. 6d. per dozen blooms may be obtained, but after the middle of February prices drop rapidly.

**CHRYSANTHEMUMS.**—The prices for blooms produced by the rough-and-ready cultural method as practised generally in market gardens have probably reached their lowest point. Those who grow large quantities may be content with a very low profit per plant, but the small grower can scarcely find it worth his while to produce blooms for which he cannot obtain much more than 1s. 6d. per dozen good bunches. Those who have but a limited space that they wish to utilise to the best advantage in autumn or early winter would certainly do better to grow their plants in pots for the production of larger, well-formed blooms. Pot culture naturally necessitates the expenditure of a much greater amount of labour, and for this reason it is not taken up generally by those who wish to get something out of their glass houses at a time when otherwise they would be empty. Planting out is so easily done, the plants needing but little attention through the summer months, with but a bi-weekly watering when housed, that even at a low price a certain amount of profit may be reckoned on. This is not, however, the way

to make the most of the space, which can only be utilised to the best advantage by growing blooms of superior quality. It is only specimen flowers that make good prices now, and these, of course, cannot be obtained except by means of pot culture.

**GRAPES.**—Hitherto the *Gros Colman* has commanded much higher prices than other black Grapes, but those who have been planting this Grape to the exclusion of the *Alicante* and *Hamburgh*, or have been rooting up the latter to make room for its larger-berried rival, will have no great reason to rejoice in having done so. The comparatively high prices which the *Gros Colman* has made in the London markets will soon be a thing of the past, the probabilities being that they will range at this season at least but little higher than those obtained for the *Alicante*. Really good samples coming from some of the best Grape growers in the home counties have been selling in Covent Garden at about 1s. 6d. per lb., whilst good *Hamburghs* and *Alicantes* have made about 1s. per lb., extra good samples making 6d. per lb. more. When the numerous Vines of *Colman* that have been planted of late have come into full bearing, the difference in price will be still less. As a late-keeping Grape the *Colman* stands well above all other black varieties, and only those who let it hang until February can hope to gain much advantage from its culture. It is more expensive to grow than the *Alicante*, requiring a longer season to ripen in, and is, moreover, much more uncertain than that reliable variety. I fail, therefore, to see what advantage is to be gained by growing *Gros Colman* for a main supply, for even if it makes a little more, this advantage will be counterbalanced by the greater expense and uncertainty attending its culture. It is rather curious that *Muscats*, which made this year from 1s. 9d. to 2s. 6d. per lb., advanced in value at the beginning of November to 3s. and 3s. 6d. per lb. One would have thought that the past summer having been so favourable, *Muscats* would be more than usually good and plentiful. This Grape is undoubtedly still the best paying kind when it can be grown in really good form, but I fail to see what advantage there is in producing *Muscats* that make no more than a good sample of *Hamburgh* or *Alicante*.

J. C. B.

## PUBLIC GARDENS.

## CHRYSANTHEMUMS IN THE PARKS.

## FINSEBURY PARK.

THE *Chrysanthemum* show properly so called at *Finsbury Park* is to be found in the old *Chrysanthemum* house close to the Manor House entrance to the park, a fact necessary to be mentioned because there are about a dozen showy groups of all sections of the popular favourite arranged with *Palms*, *Ferns*, and the like in the rather larger tropical house, which is a somewhat conspicuous building. The main collection consists of about 2000 plants, and they are placed in a wide, low span roofed glass structure admirably suited for their reception and about 100 feet in length. A single bank runs down the middle of the house with a slope each way and a path right round the sides of the house. The colours are very bright and attractive in this northern park, but white and yellow appear to predominate. Along the front of the bank of colour a row or edging of pretty little bush-grown pompons is arranged, which helps to lend an artistic feature to the display, which may also be seen at some of the other public exhibitions in the parks. Novelties are not the great feature in the parks, but good old standard sorts and a fair sprinkling of the new introductions may be found here as elsewhere. *Etoile de Lyon*, large and fine; *Col. W. B. Smith*, very rich in colour; *La Triomphe*, also large; *Florence Davis*, the pretty golden bronze *Source d'Or*, and the deep rich crimson *G. W. Childs* are grown in quantity. For a dwarf front row plant

the pale pink Mlle. Mélanie Fabre is usefully employed, and at intervals very freely grown plants carrying a large number of blooms of M. Chas. Hubert and Ile des Plaisirs are judiciously interspersed. White Japanese of good form and size are numerous. Old Elaine is a valuable variety; Avalanche, Mlle. Marie Hoste, Stanstead White, Viscountess Hambleton, Eynsford White, Mme. Isaac, Marquis de Paris, M. Astorg, &c., will tell their own tale. Good yellow varieties of the same section are represented by many fine blooms of Golden Gate, very deep and pure in tone; Sunflower, J. S. Dibbins, Admiral Symonds, a fine single-flowered Japanese, pure golden yellow and having very long florets; Gorgeous, Mr. C. E. Shea, the pale yellow sport from Mlle. Lacroix; old Peter the Great, Curiosity, once a popular show variety; J. H. Runchman, a fine deep golden yellow Japanese incurved, globular and solid, and only brought out about two years ago. Others, like Viviani Morel, its rosy bronze sport Charles Davis, Comte de Germiny, Prest. Borel, Edouard Audiguier, very rich purple-amaranth; Margot, Mrs. C. Harman-Payne, William Seward, Louise, M. Bernard in their various shades of colour all help to enliven the display, and are good in size and in purity of tint. Philadelphia here, as everywhere else, is of a pale sulphur tint and by no means imposing; Good Gracious, with its curiously twisted tubular florets, is very large, and Jeanne Délaux, a deep dark crimson variety, with narrow florets, never wanting at the shows ten or twelve years ago, still proves valuable from a decorative point of view. Shasta is novel in appearance; it has very fine tubular, erect florets, and of course is a Japanese, as such curiosities always are. Sarah Owen; Violet Rose; an old friend, The Cossack; International, always large, coarse, and varying in colour; Mlle. Lacroix, Duke of York, W. Tricker, and many more well-known varieties, both ancient and modern, are all represented. If the collection comprises so many of the Japanese, it must not be inferred that other sections are neglected. Incurved are grown in profusion, and a fair sprinkling of the Anemone section also lend a special interest to the group. These are placed at intervals and all the varieties are neatly labelled, which seems to be much appreciated by many of the visitors. The Rundles and Queens need no mention, for they are always easily recognised; so, too, are the Beverleys. Baron Hirsch, M. R. Bahuant, Prince of Wales, Guernsey Nugget, Jardin des Plantes, Barbara, Refulgens, and standard incurved of that type are all well done, and although somewhat stiff and formal compared with their rivals, the Japanese, are none the less interesting when seen in large mixed collections like those provided by the London County Council. In the reflexed section, Dr. Sharpe and Cullingfordi are the most noteworthy, and, with the exception of Louis Boehmer and Hairy Wonder, the hairy section do not seem to make much of a show, as they do at Southwark. Anemones are capably grown, and all of them show well-developed centres, upon which the beauty of that section, whether of the old Chinese or the more modern Japanese type, so much depends. A faulty centre is a defect not to be looked over in these neat and attractive varieties. Descartes, a Japanese Anemone of large size, having long ray florets and the colour deep velvety vinous-crimson, is very fine. Judge Benedict, pale yellow centre, with white or blush ray florets; Delaware, white and yellow; M. Charles Lebocqz, a pale yellow self; and old Gluck could scarcely be seen in better condition. Altogether the Finsbury collection may be said to be dwarf in habit, sturdy in growth, well flowered, very clean and bright in colour, and most of the blooms of good size and substance, and reflect great credit on Mr. Merville, the superintendent, under whose charge they are.

#### VICTORIA PARK.

Here, too, under the superintendence of Mr. J. W. Moorman (an old Chrysanthemum enthusiast), is a fine collection arranged in a span-roof

house, but of rather higher pitch than the one at Finsbury Park. Mr. Moorman breaks up his somewhat extensive collection (comprising between 300 and 400 varieties) into two large banks with a central path, and the 2000 plants forming his collection, although open to the public since early in October, is still at the time of writing these notes not past its best. Chrysanthemums have been grown for many years at Victoria Park, but the present annual display under glass is only the eighth of its kind. The plants slope down from the sides of the greenhouse in an undulating sweep until each group almost reaches the ground, with a very pretty edging of pompon varieties to bring it to an end. These are bush-grown and very freely flowered, and in point of colour are perhaps even more striking than those seen elsewhere—a remark that is equally applicable to the entire collection, for deep rich crimson varieties, purples, chestnut-bronzes, dark and rosy amaranth shades of colour have been very freely mingled with the pale tones of white and yellow which are usually so striking in most large groups of the autumn queen wherever met with. These pompons are mostly the Cedo Nullis (lilac, white and golden), Bob, Mme. Montels, Sœur Mélanie, Florence, Gen. Carrobert, Mr. Astie, Mlle. Marthe, Dick Turpin, Aigle d'Or and Brilliant. Another little gem employed to lighten the somewhat massive appearance of the large Japanese is Mlle. Elise Dordans, a pretty perfect little bloom of a pale pink shade, and when slightly disbudded is always neat and attractive. This Mr. Moorman has employed very wisely in the manner indicated, and the general effect is much improved. The collection is strong in Japanese, but as an old cultivator, Mr. Moorman does not confine his energies to that group, and we were not surprised to find a somewhat select collection of incurved, many of which we have not noticed at any of the other public displays. John Salter, Gloria Mundi, Prince of Wales and Miss Violet Tomlin are conspicuous varieties of the old show type, while Plenipo (an old rosy purple variety) and Sir Stafford Carey (chestnut-purple) were at one time much more widely known and grown than now. Newer and richer additions have been made to the incurved section like Baron Hirsch, C. B. Whinnall, &c., and these are also well done. Besides the Queens and the Rundles, Mr. Moorman's collection comprises Jeanne d'Arc, Hero of Stoke Newington, the Beverleys, old Cherub, the rich and always perfect Barbara, Lady Slade, Director Kowallek, large in size and of a pale pink, passing to white; Mme. Darrier, Rd. Parker, and many more which will be recognised by admirers of that somewhat stiff and formal group. Gluck, the yellow Anemone, is grown in quantity and is uniformly good. George Sands is another of the same type, and the reflexed section finds representatives in the old purple-amaranth sweet-scented variety Progne, the rich crimson King of Crimson and Cullingfordi. Japanese of all types from medium-sized reflexed flowers, like Margot and Roseum superbum, to huge mop-like varieties, such as International, are grown in abundance. The new Philadelphia, pale sulphur, and disappointing as elsewhere, is on view. Well-known crimson-like Wm. Seward, J. Shrimpton, G. W. Childs, Mr. J. Laing, Cesare Costa, combined with very rich shades of purple and purple amaranth to be found in old-established varieties like Edouard Audiguier, Alberic Lunden, R. C. Kingston, Mme. de Sevin, Mrs. E. W. Clark, and the newer, but velvety rich purple Deuil de Jules Ferry help very materially to enrich the appearance of the Victoria Park Chrysanthemums as a whole. There is in this section a greater variety than at Finsbury. Criterion, golden buff or cinnamon, is large and fine; Lord Brooke, finely incurved, is also in excellent form, and in similar shades of bronze and yellow Charles Davis, Sunflower, Col. W. B. Smith, W. H. Lincoln, Val d'Andorre, Charles Blick, Mrs. Dr. Ward, Golden Gate, M. Ch. Molin, and Grandiflorum are examples of the diversity of form and colour that those two shades can combine. Avalanche, the white Japanese, well known to frequenters of exhibitions; Fair Maid of

Guernsey, same colour; Louise, Florence Davis, with its peculiar greenish centre; J. W. Moorman, creamy white; Mlle. Lacroix, La Meije, a fine novelty of the same colour, introduced last season, all assert their claim to be considered noteworthy varieties in whites. W. Tricker, bright rosy pink, and Mrs. C. Harman-Payne, large rosy mauve, belong to an equally valuable group. Hamlet, salmon-cerise, should always find a place in a decorative group, and Mlle. Mélanie Fabre, dwarf, and of a deep rosy pink, comes in handy for one of the front rows. There is such a wealth of floral material at Victoria Park, that this article might be usefully extended to greater length as having a special interest for those who grow for purposes of decoration, but we have, perhaps, said enough to indicate in a measure a number of varieties with their approximate colours which may be brought together for effective and tasteful arrangement.

#### CHRYSANTHEMUMS AT WATERLOW PARK.

THE disused vineries in which the Chrysanthemums are here housed are daily thronged with visitors, and by this means a grand object-lesson in the grouping together of colours is given. All sections of the Chrysanthemum are grown here. Japanese, incurved, Anemone, reflexed, and pompons are represented each in many colours and in a variety of forms. That a stimulus is given to horticulture by such exhibitions there is no doubt. The County Council are therefore to be congratulated in having achieved a successful issue. What is wanted at Waterlow Park is a better place in which to house the plants during their blossoming period, and also a greater number of the newer varieties. Novelty in the form and colour of the Japanese kinds in particular is what maintains the keen interest of the Chrysanthemum enthusiast, and if this is to be experienced in a greater degree by the general public, it should be considered the duty of those responsible to provide places of public resort, such as the one under notice, with an extra number of new sorts each season. In this way the interest is encouraged. This thought occurred to me when noting the sorts grown at Waterlow Park, so few of the new varieties being represented. Some of the best Japanese flowers seen here were J. Shrimpton, in better form than seen since its introduction, its bright crimson blossoms on very dwarf plants standing out prominently. Gloire du Rocher, crimson and shaded yellow, had large flowers. W. Seward, deep crimson, was very effective. Mme. Isaac, with large, creamy white flower and broad petals, was pretty, and good specimen blossoms of Commandant Blusset, carmine; W. H. Lincoln, yellow; Comte F. Lurani, rose, shaded white, very dwarf; Miss Dorothea Shea, bright red, flushed yellow, on a late bud; and some extra good blossoms of Puritan, with its broad incurving white petals, tipped rosy mauve, were amongst those specially admired. Two good decorative sorts were noticeable, the blossoms being freely produced, viz., Alex. Dufour, rosy purple, dwarf, and October Yellow. The Anemone section was represented best by even and clean blooms of M. Charles Lebocqz, colour citron-yellow, tinted carmine. Of the incurved varieties, Jeanne d'Arc, Mr. Bunn, Beverley, and Mme. Darrier were worthy of extra notice, the last-named, one of the finest acquisitions of recent years, colour nankeen-yellow, being specially good. The charming medium-sized incurved blossoms, represented by Mrs. Geo. Rundle, white; Mr. Geo. Glenny, very pale yellow; and Mrs. Dixon, golden yellow, illustrated the pleasing form and colour of these easily grown sorts, and, taken together with their free-flowering qualities, proved at once their value as the best of the decorative kinds. Anemone pompons were seen in freely flowered plants of Marie Stuart, pale lilac outer florets, light yellow disc, and its pretty and chaste white sport Emily Rewbottom. The general pompon section was best represented by Elise Dordan, with pretty light

rose-coloured globose flowers; Howard H. Crane, brightest crimson; William Westlake, bright yellow; and Golden Mme. Marthe. Each of these sorts was allowed to produce its blossoms quite freely; consequently when placed here and there amongst the larger flowering kinds, they formed a nice break in the somewhat formal arrangement of grouping practised here. Masses of *Aster Amellus bessarabicus* with its pretty blue flowers were placed to advantage throughout the houses, and formed a pleasing contrast to the surroundings. A large number of early-flowering *Chrysanthemums* are planted in beds and borders in different parts of the park, and these have kept the place quite bright during the autumn. One of the very best varieties is Percy's Seedling, a dwarf, free-flowering pompon of a bronzy yellow colour. C.

**Open spaces.**—The monthly meeting of the Metropolitan Public Gardens Association was held at 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding. It was announced that Mr. H. C. Richards, M.P., had agreed to provide funds for placing some gymnastic apparatus in the recently-opened ground, Bartholomew Square, E.C., that the London County Council had declined to sanction plans for the erection of houses on the vacant site in Compton Place, W.C., and that the association had taken part at the recent inquiry held by the Charity Commissioners in opposing the proposed demolition of the Trinity Hospital and Almshouses, Mile End Road. Plans for the laying out of St. James's Churchyard, Piccadilly, a burial-ground in York Street, Walworth, and the ground by St. Matthew's Church, Fulham, were considered, and a letter was read from the vestry of St. James's, Westminster, with regard to the first-named ground. It was announced that the garden laid out by the association in Quadrant Street, Canning Town, E., had been opened to the public, and that the churchyard of St. Leonard's, Shoreditch, had been taken over by the vestry as a public garden. It was agreed to offer £500 towards the acquisition, and £500 towards the laying out of the Guy's Hospital disused burial-ground in Bermondsey. A large number of other matters engaged the attention of the meeting, including the preservation of an open space at Ham in connection with the Bill deposited by the Dysart Trustees, the acquisition of the Copperas, Bromley, and of the Millbank Prison graveyard and other sites, the opening of Charterhouse Square and the planting of trees in the boxes by the Royal Exchange and in a site in Mayfair.

**The Vine weevil.**—Will someone tell me how to get rid of, or keep down, the maggots, a few of which I send? I should also like to know the name. There are two or three in the box that are passing into another stage; are they beetles when developed? They seem to get at the roots of *Polyanthuses* and *Primroses*, and make their way to the heart of the crown, totally destroying the plants. This year they appear to be more numerous than ever. I have also found them attacking *Saxifrage* and similar plants.—ZEMO.

\*\* In reply to the above, the maggots you send are the grubs of the black Vine weevil (*Otiorynchus sulcatus*), a common and most destructive pest. When a plant is attacked by these grubs there is nothing to be done but to shake it out and pick out the grubs. Any insecticide is so weakened by passing through the soil, and it is so uncertain if it will soak in any quantity to where the grubs are, that it is of very little use trying to use one. The most effectual way of "stamping out" this insect is to kill the weevils, which are nearly as destructive as their grubs. They feed on the foliage of various plants—Vines, Peaches, Strawberries, and many plants which are grown for the sake of their foliage. Unfortunately, they only feed at night time, and during the day hide themselves so cleverly that it is almost impossible to find them. Any plants which it is supposed have been injured by this weevil should be placed on a white sheet during the day. If

they can be laid on their sides so much the better, as when the weevils drop they will not fall on to the dark earth, and after dark as bright a light as possible should be introduced suddenly; this will probably cause the beetles to fall on to the sheet. If the weevils do not fall, the plant should be smartly shaken and well searched. Small bundles of dry Moss or straw should be tied to the stems of the plants and laid on the mouths of pots, into which they might creep and hide. The beetles are each about three-eighths of an inch long, somewhat pear-shaped, and almost black. Another kind, whose grubs are very similar to those of the black Vine weevil, is clay-coloured, and known as the clay-coloured weevil (*O. picipes*). It is just as destructive as its relative.—G. S. S.

**Removing greenhouses erected by tenants.**—I am going to put up a small greenhouse about 20 feet long as a tenant's fixture, and should be very much obliged if you could inform me which is the best and cheapest method of doing so. I must be able to remove it when I leave, and to be quite sure it is not a fixture to the land.—E. H. M.

\*\* The general rule of law is that whatever is affixed to the demised premises by the tenant can never again be severed without the consent of the landlord. This rule has become largely modified, but the exceptions may be ranged in three classes: (1) Fixtures erected for ornamentation and convenience—usually removable when removal can be effected without damage to the freehold; (2) fixtures and buildings erected for trade purposes—for the carrying on of trade—which may be removed by the tenant; (3) fixtures and buildings declared by statute removable upon certain conditions, as under the Agricultural Holdings Act, 1883, and the Market Gardeners' Compensation Act, 1895. Applying these rules and enactments to the case of a greenhouse, it may be said that such an erection upon a market garden or upon an agricultural holding may be removed during the tenancy upon the expiration of a month's notice given in writing by the tenant to the landlord, provided certain minor conditions are observed. But the case of a greenhouse erected by a private occupier for his private use is a very difficult one. Such an erection is not for ornamentation, nor for convenience, even though removable without injury to the freehold. There is no case in which the plain issue has been decided in a court of law, but the best writers on the law of landlord and tenant consider the point very doubtful, and some incline against the tenant's right of removal. The safest plan for a tenant who wishes to erect a greenhouse for his private use is to obtain the written consent of his landlord before erecting it, such consent to include the right of removal. Failing this, he should take care to make the foundation separate from the building itself, and then allow the greenhouse to rest upon the foundation by its own weight. The use of brick or cement for a foundation is not safe if the erection is secured thereto, but if such materials as old railway sleepers or other timbers were laid upon the ground and the greenhouse was bolted to them, it would be clearly removable, not merely as a fixture, but as a chattel. Such a method would be very economical.—K. C. T.

**The weather in West Herts.**—The 15th was a warm day for the middle of December, otherwise both the days and nights during the past week have been about reasonable in temperature. On the coldest night the exposed thermometer showed only 9° of frost. The ground is now about 5° colder at both 1 foot and 2 feet deep than it was at the beginning of the month, and at the latter depth is slightly warmer than the December average. Shortly before half-past five on the evening of the 12th inst. there occurred a very sharp fall of hail. The wind, which had previously been only of moderate strength, all at once increased to a strong gale, and veered from south to west. During this sudden blast, which lasted only a few minutes, the temperature of the air fell as much as 8°, rising again 2° directly the

hail ceased. Lightning was also seen and thunder heard. The 13th was a very rough day, the mean velocity of the wind for the seven hours ending 5 p.m. being 29 miles an hour. Between 1 and 2 p.m. a velocity of 31 miles was recorded, direction west, making this the fourth day during the month when the wind has risen to the force of a gale. On seven of the last ten days no sunshine at all has been recorded.—E. M., *Berkhamsted*.

## NOTES OF THE WEEK.

**Winter-blooming Crocuses.**—The vivid orange-coloured *C. vitellinus* and the pale *C. hyemalis* have been in flower for several weeks, and are even yet bright on sunny days, notwithstanding heavy rains and rude winds. *C. Imperati* has also just opened its fawn-coloured buds to the wintry sunshine. *Narcissus Tazetta* var. *remopeliensis* and one or two others have also been in bloom for some weeks under a warm wall.—F. W. B.

**Thunbergia grandiflora.**—Mr. Lakes sends us from his garden at Trevarrick, St. Austell, a handsome spray of bloom of this *Thunbergia*. He says he finds it a free bloomer, and at this time of the year very useful. At Kew this plant also does well in the Palm house, and is also at home trained along the roof of the Victoria Regia house. The flowers are of a pale blue, lined with a deeper tint, the interior of the throat almost white. There is also a white form of it. A coloured plate of the two forms was given in THE GARDEN of March 2 of this year.

**Skimmia japonica.**—This exceedingly pretty berried shrub makes a very useful subject for pleasure ground borders, but should not be planted in poor soil, as it is rather a slow grower. Associated with such things as *Kalmias* and *Andromeda floribunda*, it has a cheerful appearance at this season of the year. I have never known blackbirds and thrushes take the berries, this fact indicating that there is some property in them injurious even to the feathered tribe. The berries of this shrub and those of the Deadly Nightshade are the only ones, so far as my knowledge goes, that birds refuse to eat. The *Skimmia* grows all the better if a fourth part peat is mixed with the compost.—J. C.

**Calycanthus floridus** (Allspice Tree).—Mr. Burrell complains of having been supplied with a scentless form of this plant. As long ago as 1836 Loddiges' catalogue contains a list of six varieties, amongst which is one named *inodorus*, from the fact of its flowers having no scent. Leudon in 1842 quotes these, and also gives two other varieties of *C. floridus*. He further mentions that *C. glaucus*, *C. g. oblongifolius*, and *C. lævigatus* have all much less scent than *C. floridus*. I have an impression that the large-flowered *C. macrophyllus*, which was introduced in 1848, is not so highly perfumed as the original species, which has been known in our shrubberies since 1726, and which from the number of its named forms is evidently a very variable species if raised from seed.—W. T., *Bishopsteignton*.

**Aristolochia tricaudata.**—This quaint and somewhat rare species from Mexico is now flowering with me. It is curious to notice how this plant develops flowers near the soil on its old hardened wood stem, as well as on the last and yet green growth. This peculiarity it has in common with some few other species. The flowers remind one of those of *Masdevallia Chimara* being split into three tails each 4 inches long and somewhat twisted. The colour is a brown-chestnut. The light green leaves are each about 7 inches long by 3½ inches wide. It can be propagated by cuttings inserted in sandy peat, with a good bottom-heat under a bell-glass. Good cuttings are scarce, as the plant is rather a shy-branching one. For the stove at this dull season of the year it is a curiosity not out of place amongst Orchids, as *Calanthe Veitchii*,

*Cattleya Trianae*, and *Trichopilia tortilis*, which are now coming into bloom.—J. SALLIER, Paris.

**Randia macrantha.**—In the Palm house at Kew there is now a large specimen of this rare stove plant in flower. It is nearly related to the *Gardenias*, and especially to *G. Stanleyana*, which is, indeed, now looked upon as a *Randia* too. It is a bush 5 feet to 6 feet high, with leaves 4 inches to 6 inches long by about one-third as much in width, and of the dark glossy green familiar to us in the foliage of the common *Gardenia*. The flowers are peculiar in shape, resembling a long and slender trumpet. Each one has a corolla about 10 inches in length, the tube of which for the lower two thirds of its length is no thicker than an ordinary penholder. The spreading and slightly recurved lobes are ovate, and the colour is a pure creamy white. The flowers are borne singly on very short stalks terminating the branches. *Randia* is an extensive genus, containing upwards of 100 species, many of which are natives of Africa; others, however, are found in Asia and tropical America. *R. macrantha* is a native of Sierra Leone.

**Pears President Barabe and Beurre Rance.**—The editorial note on President Barabe Pear as sent by Mr. Allan, of Gunton, is interesting, as it proves that the limited list of later varieties is gradually increasing. I cannot, however, agree with the assertion that to grow Beurre Rance is to waste precious space in our gardens. Here in South Notts this old Pear ripens satisfactorily in five seasons out of six, and is on our soil better flavoured than *Josephine de Malines*. Probably it will be found that the flavour of President Barabe, like that of other late Pears, is much affected by indifferent seasons. I have sent several fruits of Beurre Rance for you to taste.—J. CRAWFORD, *Cedlington Hall, Newark*.

\*\* We thank you very much for sending us the finest B. Rance we have seen in England. The flavour of the Pear, as tested by the fruit sent, does not equal that of President Barabe, Winter Nelis, Easter Beurre, or Doyenné du Comice. The flavour is somewhat watery and the flesh gritty as compared with that of the best Pears.—E.D.

**Nepenthes Rajah.**—A robust and healthy specimen of this now rare Bornean Pitcher Plant is at present to be seen in the private house devoted to cool Orchids, &c., at Glasnevin Botanic Gardens, Dublin. The plant has two fine new pitchers and several old ones, while there are very healthy points to some of the younger leaves, betokening their future development into gigantic urns. The pitchers of this noble species when fully grown each hold three to five pints of water. They are of a stout leather-like substance and texture, and of a brownish purple colour below, the glossy rim or mouth of the pitchers being of a rich red-brown hue. The midrib emerges from the thick leaf apices in a peltate manner, thus differing from all other species in which the midrib is prolonged from the points of the leaves. In the same house are healthy plants of the *Cephalotus follicularis*, a very large pitcher and highly coloured form, and also specimens of the Sun-cup, or *Heliamphora* of Guiana, one example of which bloomed here some time ago. Mr. Moore is an adept at rearing rarities, and has a healthy little colony of seedlings of the rare *Rovivula gargonis*, a plant resembling *Drosera lusitanicum*.—F. W. BURRIDGE.

**Erigeron mucronatus** is a hardy, graceful, ever-blooming plant that might often be used with good effect as an edging, either to permanent groups or to arrangements made for the summer only. Its flowers are no larger than those of the common Daisy, but they have a beauty all the same, and throughout the year come with a persistency that is only checked by the approach of winter, and even now, in the last month of the year, there are still many flowers open upon an edging of several years' standing that margins a bed of standard Roses and Carnations in the flower garden at Betteshanger Rectory. Those who are

seeking for something that will give an agreeable and pretty change from the conventional edging plants may well be advised to give this a trial. Not only is it hardy and ever-blooming, but it sows itself from seed freely, so that an unlimited stock can be quickly obtained. The surface of the bed above mentioned was green with a crop of young plants that have sprung up this autumn, the seed from the earlier flowers having been wafted all over the bed by wind. This plant has all the essential qualities of an edging plant, as it makes a perfect unbroken line, whilst its habit is slender, graceful, and informal when untrimmed. It is seen to the best advantage as an intervening line between grass and flowers of bright colour.

**Leycesteria formosa.**—It is astonishing that a distinct shrub of so free growth and easy propagation as the above should not be more generally planted throughout the country, for distinct from the ordinary run of flowering shrubs it certainly is, and blooming late, even through a great part of the winter, its reddish purple, pendulous bracts, contrasting with the polished green shoots, are attractive, especially so on bushes that have attained a goodly size. In parts of the country where the severity of some winters might kill it to the ground line, it should not be excluded from the collection, for undoubtedly the hard-pruned bushes—either by knife or frost—produce larger bracts on shoots emanating from the base of the plant than on those from older wood. Neither is it a plant particular as to soil, though I believe it thrives best in light, open soil, fairly enriched. Its propagation is of the simplest. Tolerably long-ripened shoots of the current year, inserted deeply in sandy soil in the open in November—the same as Gooseberries and Currants are propagated—will strike and form good roots within the twelvemonth. As soon as put in, the cuttings will be all the safer of a mulching of spent Mushroom manure or any light frost-resisting material.—J. F.

**Helleborus niger var. altifolius.**—The *Chrysanthemum* monopolises so much attention now that little thought is given to any other flowers. A plant that will enliven the dullness of December days out of doors and make a picture, with little care or attention, surely deserves to be brought out from the comparative obscurity in which it lives, have its merits proclaimed and its numbers increased, so that all who desire it can have it in quantity. All who know the fine Christmas Rose that goes under the above name are agreed that it, before all other forms, deserves good treatment at our hands, yet how rarely do we see it good, and still more rarely in quantity in either gardens or nurseries. It gives us several weeks of beauty before the colder days of winter set in. At Betteshanger Park, near Dover, we recently saw a fine lot of this Christmas Rose, strong in growth and abundant in blossom, many of the finest flowers borne on stems nearly a foot above the ground. The chalky loam of the district is no doubt congenial to it, but there are hundreds of gardens where it would grow as well, and whether seen in the garden or cut and carried into the house it is as choice and lovely as the Bermuda Lily or the Eucharis, and altogether more lasting. A coloured plate of it was given in THE GARDEN for July 6 of this year.

**Cattleya luteola.**—This is a small, but pretty species, which in these days when so many fine *Cattleyas* and *Laelias* have been added to the list of cultivated Orchids is not unlikely to be passed over. It would be a pity were it to disappear entirely from our collections, for although small—perhaps the smallest of all *Cattleyas*—it has a modest beauty of its own, and besides this it flowers at a season when it is most welcome, viz., December. It has one-leaved pseudo-bulbs, which are about 2 inches high, the leaf being about twice as long. The flowers, of which three or four appear on each spike, are of a pale yellow, and measure 2 inches across. The middle lobe of the lip has a white margin, and the side lobes are striped with dull reddish purple. The species has

been in cultivation for upwards of fifty years, having first appeared with Messrs. Backhouse, of York. It is a native of Brazil, and is sometimes grown as *C. Hoffordii*. It requires the usual *Cattleya* treatment as regards compost and temperature, but on account of its size is better grown in a basket and suspended near the roof glass than in a pot. The variety *Roezlii*, which was discovered by the collector whose name it bears in Peru about 1874, has more brightly coloured flowers than the type, and there are two large purple spots on the lip.

**Dendrobium bigibbum.**—Of all the Australian *Dendrobiums*, which are more numerous than their rarity in gardens would lead one to imagine, this species is, I think, the most beautiful. Unfortunately, it is not one of the easiest to grow, and usually deteriorates in vigour a few years after importation. Although the height of its flowering season is now past, it may still be seen in bloom; indeed, where a few plants are grown its flowers can always be had throughout the last three months of the year. The flowers are produced on a long raceme, and have much the same pose as those of *D. Phalaenopsis*, now so much grown. They are smaller than those of that species, being about 2 inches in diameter. The sepals and petals are of a rich warm purple, with a thin thread-like line of white running round the margins. The lip is of an even richer purple, the side lobes turning up over the white column. The flowers have a compact, full appearance, owing to the overlapping of the segments. It was originally introduced from Australia in 1824, and a drawing of one of the original plants made by the famous botanical artist, Francis Bauer, is preserved in the British Museum. Coming from one of the sunniest regions of the globe, it should be given all the light possible, and during growth it requires the warmest and moistest conditions available.—B.

**Moss on lawn (Anxious).**—Use sulphate of iron in the proportion of 1 lb. to two gallons of water. The solution should be made in a wooden tub or barrel. It should be made with soft water, and also just before using it, as it loses strength if kept. It can be applied at any season. When the Moss begins to turn black, this shows that the sulphate is taking effect. If the Moss only turns red, a second application will be necessary. Seeing that Moss indicates poorness of soil, it will be advisable to give the lawn a good top dressing after the Moss has been destroyed.

**The national testimonial to Mr. A. F. Barron.**—I should like to suggest, quite unofficially, of course, that the secretaries or treasurers of the numerous horticultural societies should be courteously requested to obtain permission to make some contribution to this fund. It is not so much the amount of the subscriptions as their wide and representative character in a case of this kind. Some of us are of the opinion that this testimonial should be really a national one, as a genial expression of fellow-feeling for one of the most generally respected members of our profession. It would be a further act of graceful kindness if the council of the R.H.S. would make some special grant as a beginning to this fund, and it would no doubt be taken as a fitting emphasis of their courtesy in recently having offered a life fellowship to Mr. Barron. The hon. treasurer of the fund is Mr. H. J. Veitch, F.L.S., and all subscriptions, &c., should be sent to the hon. secretary, Mr. B. Wynne, 1, Danes Inn, Strand, London, W.C.—F. W. BURRIDGE.

*Inquirer.*—"Oliver's Elementary Botany" will answer your purpose.

**Names of plants.**—*W. W. H.*—1, too poor to identify; 2, *Origanum Tournfortii*; 3, *Artemisia tanacetifolia*; 4, *Salvia splendens*.—*W. A. G.*—1, *Onocidium divaricatum*; 2, *Onocidium tigrinum*.—*C. Mounsdon.*—A very good lot of flowers.—*F. Williams*—1, *Adiantum emarginatum*; 2, *A. petatum*; 3, *Feris erchia* all-oblincata; 4, *Asplenium viviparum*; 5, *Nephtrolepis exaltata*.

No. 1258. SATURDAY, December 28, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## STOVE AND GREENHOUSE.

## EUCHARIS FOR MARKET.

IN all the great centres of the cut-flower trade the Eucharis is ever in the front rank. It is, in fact, indispensable in almost any and every floral arrangement where choice flowers may be used. Perhaps one of the grandest pictures among stove-flowering bulbs is a houseful of Eucharis in bloom. Even in a market nursery the flowering continues for some time, generally from a fortnight to a month from the first gathering, where the blooms are taken singly as they expand. Much of this, however, depends on the wants of the market at the moment, and also the time of year at which the flowers are ready. It is only natural with any flower so constantly in demand and so popular in all our large markets that there are men to be found who not only make these flowers a sort of specialty, but who also endeavour to maintain a supply throughout the greater part of the year. The grower who is capable of so much quickly creates for himself a name. Unless a man is possessed of capital for the purpose, it is a question of time to work up a stock of Eucharis, that is, a stock sufficient for the purpose indicated. To devote a series of houses to Eucharis alone and at the commencement of a business, requires not only great faith in the result, but capital to work upon till the bulbs attain flowering size. Once this is secured, the flowering of the bulbs is a comparatively easy matter in the hands of a careful cultivator; indeed, from the first their

## CULTURE

is an easy matter if attention be paid to a few essential points. These are heat, soil, watering, and resting. The first, of course, is the greatest of all in their successful cultivation, and may range between 65° and 80°, with an increase on the latter by sun-heat. High temperatures are always more conducive to health in these plants than are low ones, especially if in the latter extreme care has not been taken in the watering. Sickly bulbs quickly follow on continually low temperatures and much water at the root. As a rule, in market nurseries where these plants are grown to any extent very large pots are avoided and bottom-heat, as usually understood, dispensed with. Pots of about 9 inches to 11 inches across are found quite large enough not only for handling, but are considered as conducing to continued health, by accommodating only a minimum quantity of soil. Large pots, on the other hand, are ungainly and contain a larger amount of soil than is really needful for the plant. Should this by any means become over-watered and the whole soured, the failure of the plant is all but sealed. Small pots, it is true, are very quickly filled with roots that threaten to lift the ball bodily from its place, but the plants remain perfectly healthy notwithstanding, and in this state can bear a greater share of moisture. In fact, I believe the failures would be fewer if smaller pots generally were employed, and I know from experience that good flowering bulbs may be well grown in 8-inch pots. Soil is also important, and the most suitable mixture is one mainly of good yellow loam of a

rough fibrous character, a sixth part good fibrous peat in small nuggets, Oak or Beech leaves, half decayed, at the same rate, and old mortar rubbish and charcoal nuts, at the rate of a barrowful each to every load of soil. A free addition of sharp sand and a sprinkling of soot will also be helpful. What the roots prefer is a free, open mixture of soil, and if all the fine is screened away, so much the better. Indeed, this is much the surest way of keeping the soil open for any lengthened period. Soils vary so very considerably, that the more minute details must be dealt with according to individual circumstances. Some soils always remain hard, nutty particles, that contain very little dust; others, again, while on first view appearing fibrous, rapidly break down into fine powder. Of this latter kind is much of the soil of this part of Middlesex, and this very quickly runs together and becomes sodden. Those who have the choice of soils should always try for the former kind for many things, and Eucharis in particular.

Perfect drainage is also most important, and should consist of a large-sized crock or oyster shell placed hollow side downwards; above this a layer of medium-sized pieces, and finally thin slices of freshly-cut turf, grass side down to cover the drainage completely. So far, then, I am strongly in favour of medium-sized pots, a limited amount of comparatively rough soil, which always remains in a sweet condition much longer than the fine soil, and, third, perfect drainage. But now a word about

## BOTTOM-HEAT,

or rather why it should be dispensed with, as is done in most market nurseries. As a matter of fact no one really finds fault with the bottom-heat alone; it is the materials usually employed in the bottom-heat that are really injurious. Plunging in bottom-heat is indeed part and parcel of a bygone time for these stove plants, and however helpful or necessary it may be in the forcing or propagating department, which is only temporary, is neither necessary nor helpful to healthy growing plants, and, more than this, it is not conducive to a healthy root action. To keep the roots of any plant, stove or what not, permanently in a higher temperature than the foliage is in distinct opposition to Nature, and must sooner or later fail; and use what we may, fibre or tan, there is always a decay going on around what should really be the healthiest part of the plant. Moreover, any plunging material must quickly sour unless frequently renewed, while its very presence stifles, so to speak, the healthy functions of the roots. Plunging in bottom-heat I only countenance for bulbs that have been a long time dry or to resuscitate sickly stock. Much the simplest way of growing these plants, and one that finds favour among the market growers, is on simple wooden stages. The least expensive kind is made of wooden uprights and cross bearers, with narrow strips of wood 3 inches or 4 inches wide nailed upon them. Upon these open stages the plants are grown, the pipes being distributed beneath. In this way the houses are heated uniformly and in such a manner that no plant receives any excess. Upon these open stages souring and its attendant evils are very rare. By a rap at watering time the condition of any plant may easily be determined, a thing by no means easily accomplished when the plants are plunged. During the growing season floors and stages are kept in a state of semi-saturation and overhead in proportion. Where much syringing is done overhead very little root watering is needed, owing to the leaves and leaf-stalks, which constitute a ready conduit to the roots of the plant. Indeed, some years

ago I resuscitated a large batch of these on a bottom-heat of 95° by the use of the syringe alone, and for upwards of eight weeks the plants were never watered otherwise. In some of the larger market nurseries fully a dozen or more long, spacious span-roofed houses are devoted to the Eucharis. Many thousands of plants are grown in the endeavour to maintain a never-failing supply. The least demand for such flowers is during July, August and September. Yet it frequently happens that a big "throw" will come in in one of the former two months when there is practically no demand. This has to be endured, however, simply on account of the next flowering of the same batch, which generally makes amends for the summer loss. During summer the plants are rested materially from fire-heat and heavily shaded from the sun with permanent shading or roller blinds. Another large item where the Eucharis is extensively grown for market is found in picking, sorting and packing the blooms. When the Eucharis is in full swing it is quite an every-day occurrence for one large grower alone to market 200 or 300 dozen blooms, a considerable item to dispose of in one morning before breakfast, as it were. Eucharis blooms are not usually sold in bulk, but in small quantities, and are packed a dozen and a half best, or two dozen seconds into shallow boxes about 7 inches wide, 3 inches deep and 1½ feet long, a layer of green Moss in the bottom, and afterwards neatly lined with white tissue paper. An incision is then made with a small penknife in the bottom piece, and the tube passes through into the damp Moss, keeping the flowers fresh and in position at the same time. According to the season, the blooms are damped or the reverse. Some growers simply cover with white tissue paper, others with strips of cotton wool, skin side downwards. The latter is by no means necessary unless for a long journey by rail. Even then it is calculated to do more harm than good to the blooms, as the latter can rarely ever be freed from it when once it has come into contact with them. E. J.

**Camellia Sasanqua.**—Two years ago a first-class certificate was awarded to this Camellia from specimens sent by Messrs. Veitch, of Chelsea, who at that time stated that at Coombe Wood it had proved to be hardier than the ordinary Camellias, and also set its buds more freely. As the specimens were shown on December 13, at which time the plant was flowering profusely in a cool house, it must certainly be regarded as a valuable subject for the embellishment of the greenhouse or conservatory at this season, for, even where other Camellias are grown, this is so dissimilar from the ordinary garden varieties, that it is sure to be particularly noticed. It is an old garden plant, but would appear to have almost dropped out of cultivation till Messrs. Veitch took it in hand, and in all probability it will now become far more popular. Concerning this particular species, Professor Sargent, in his "Forest Flora of Japan," says: "Sasan-kuwa (Camellia Sasanqua), a small, bushy tree of Southern Japan and China, is perhaps more commonly encountered in Japanese gardens than the Tsubaki (C. japonica), and in the first week of November (it was just beginning to open its delicate pink flowers in the gardens of Nikko, although the night temperature was almost down to the freezing point." There are several forms of C. Sasanqua, but the particular kind upon which the certificate was bestowed was that which produces single pink blossoms. A semi-double form with white flowers was shown at the same time. There is also a variety which is occasionally met with whose leaves are prettily variegated with white, but it is at times very liable to revert to the normal green-leaved type. The flowers that I have seen of this variegated kind are single pink. The foliage of C. Sasanqua is very much

smaller and the branches more slender than those of *C. japonica*. Another point of difference is that *C. Sasanqua* can be struck from cuttings much more readily than the other. It may be employed for the same purposes as *C. japonica*, that is to say, as a bush or for clothing a wall, in which latter position, if out of doors, its extra hardiness will stand it in good stead.—T.

**Celosia pyramidalis.**—This may be had in bloom at various times of the year, but in many places at least it is far more valuable during the autumn and early winter months than at any other time. The feathery plumes of brilliantly tinted blossoms are extremely useful in a cut state, and as flowering plants they will, in a greenhouse temperature, if the atmosphere is not too much surcharged with moisture, remain bright and fresh in many cases for a couple of months. For autumn flowering the seed may be sown about midsummer or a little later on, and grown on freely they will form neat flowering specimens in pots  $4\frac{1}{2}$  inches in diameter. As the bulk of flowering plants during the autumn consists of *Chrysanthemums*, these *Celosias* are extremely useful. Though liberal feeders during the growing season, these *Celosias* are very impatient of an excess of moisture as autumn advances, while the fogs often experienced in the neighbourhood of London play sad havoc with the foliage. *C. pyramidalis* is said to have been introduced from India in 1820, and now seed of its numerous forms can be obtained at a cheap rate from any seedsman. The specific name of *pyramidalis* is certainly a very appropriate one, as a well-grown specimen will often form an almost perfect pyramid.—H. P.

#### POINSETTIA PULCHERRIMA.

THERE are now several distinct varieties of this useful plant. The earliest variety has been in fine condition with me (December 7) for the past fortnight. This early variety is known as *carminata*. It is not quite so deep in colour as the later variety, and a curious fact is that, though the leaves are more lobed than are those of the late variety, the bracts are nearly always ovate, very few having any lobes, while in the other variety the reverse is the case, the leaves being ovate and the bracts lobed. The double variety *plenisima* is the latest. This will hold out until February, but it requires a good deal of care to do this well; it is of weakly growth compared with the others, and the bracts are apt to drop off before they are fully matured. It is, however, worth a little extra care, for when well done the additional bracts which come from each individual flower fill up the centre and add much to its beauty.

In growing Poinsettias, many people start the plants too early in the season. It does not matter so much where they are only required for cutting, but it is impossible to make dwarf plants with foliage down to the pots. June, or even July, is early enough to propagate, but the old plants must be looked after, so as to ensure getting good strong cuttings, or if the stock is short, some cuttings may be put in earlier and the tops of these taken later on. Short cuttings are best. They must be cut off quite close below a leaf. This is not so important when the cuttings are taken from old plants close to the old wood, but in taking tops, the stem between the leaves will be found to be hollow, and must be cut quite close to the joint where it is solid. If taken off and put in singly into small pots, using light sandy compost and a little quite dry sand at the base of the cuttings, they will soon take root and should start away without losing a leaf. Poinsettias like a good rich loamy compost. They do not require any artificial heat during the summer, but should be grown as close to the glass as possible, and if careful attention is paid to the watering they do not require any shading—in fact, the more fully they are exposed to the sun the better. Warmth must be given as soon as the nights begin to get chilly in the autumn. They will not appear to suffer from cold for some time, but as

soon as they are placed in warmth the leaves will turn yellow and drop off. I have seen plants which had been left in a cold house late in the autumn which had no appearance of having suffered, but when taken into the stove the whole of the leaves had dropped off. When the plants are developing their bracts they may be liberally fed with liquid or artificial manure, but the latter should be applied in small quantities and repeated about every five or six days. H.

#### PRUNING STEPHANOTISES.

SHOULD *Stephanotis* be pruned, and to what extent, is a question well worthy of discussion. Some growers of my acquaintance use the knife rather freely very early in the winter, and are satisfied with the results. I have tried their methods, and was dissatisfied with what followed. To me it appears to be much the same with *Stephanotis floribunda* as with fruit trees. If we want plenty of growth, prune hard, but in order to have abundance of bloom with a minimum of growth, then we must prune lightly, the pruning taking the form of thinning out rather than much shortening back. When most of the young growths made during the preceding season are cut back to the second or third joint, the resulting growths are extra strong and usually run to a length of several feet, or even yards, before showing flower; whereas if these same well-matured growths had been merely thinned out and those reserved allowed to break naturally, they would do so at nearly every joint and commence flowering at once. What experienced gardener has not seen hundreds of short growths full of lovely flower-trusses hanging down from plants trained thinly over the roof of a plant stove? Not a few who have seen these wondrous displays of *Stephanotis* failed to realise that it was owing to the treatment the plants received, and went away with the idea that it was a superior variety. If they had done as I once did, struck cuttings of a presumably free-flowering form only to find, after giving the plants a fair trial, that they were neither better nor worse than those long since established on the place, a lesson would have been learnt.

Many of us err, or have erred, in giving the plants what might be termed unlimited root-run, this leading to the formation of such a number of long and, it may be, flowerless growths, as to almost necessitate a free use of the knife at pruning time. Really grand plants have been flowered in 18-inch or smaller pots, as well as in tubs and small loose brick pits, for many years in succession, the *Stephanotis* not objecting to having its roots reduced when it is necessary to renew the soil, an operation which should be carried out just when the plants are breaking into growth. There are two methods of training the plants, viz., that of spreading the growths thinly and irregularly all over the roof trellis, and of taking the main growths or stems straight up or down the roofs and training the flowering wood across the roof, two or three going to each wire. The latter plan is far the better in every way, and is, in fact, the only one which admits of systematic training, cleaning, syringing, and such like. Each winter some of the old growths should be cut out and the young ones be laid in, and if the latter are well matured, they will break freely throughout their length, flower-trusses frequently showing at the second or third joint. In some cases embryo flower-trusses will be found in a dormant state at the joints towards the end of the young wood. They were formed too late to develop last season, but if reserved will be the first to expand next spring, proving most valuable accordingly. Cutting out old

growths will invariably lead to the formation of as many or more strong young growths, some or all of which may be laid in for the purpose of producing wreaths of flowers in 1897.

Mealy bug is responsible for innumerable failures with *Stephanotis*. Many days have been spent by most of the present generation of head gardeners cleaning *Stephanotises*, but surely the experience thus gained when young men has had the effect of inducing some at least of them not to trust the plants to the tender mercies of thoughtless journeymen and boys. Those days on the floors, in tubs of strong insecticides, and under other rough treatment, never yet thoroughly got rid of mealy bug—at least, I never found that it did—but if it failed to destroy all the bug, it never failed to greatly damage the plants. Instead of taking down the plants, unless for the purpose of re-arranging, the better plan is to thin out where crowded and then to depend upon hot water, petroleum, soft soap and the syringe for getting rid of the bug. Let the water be heated to a temperature of not less than  $112^{\circ}$ , and to every 3 gallons of this add a lump of soft soap of the size of a hen's egg and 6 ozs. or 3 wineglassfuls of petroleum. Keep the latter from floating on the top in the usual way—that is to say, by either forcibly returning every second syringe-ful into the receptacle holding the mixture or else by having two syringes going. When applied thus hot and with a fair amount of force, it will cause the mealy bug to simply melt away and prove far more effective—always provided it is done in no half-hearted manner—than any amount of sponging and brushings with and bathing in tubs of strong insecticide. The petroleum mixture is equally efficacious against brown scale. The syringe during the growing season should do the rest. W. I.

#### FLOWER GARDEN.

##### GARDEN LILIES.

TWENTY years ago Lilies as a class were not grown to nearly the same extent as they are at the present day, and the fact that many of them are so well adapted for the embellishment of the open garden was then to a great extent ignored, though it must be confessed that the grand masses of *L. candidum* and *L. chalcedonicum* at that time met with in old-fashioned cottage gardens are not surpassed, and, indeed, rarely equalled in more ambitious establishments at the present day. Now, however, many different Lilies are planted in quantity, and, among other places, we have been shown at Kew what grand effects can be produced by bold masses of them in some cases associated with low-growing shrubs. Many of them will succeed in any ordinary good garden soil, while in the case of others an admixture of peat or well-decayed leaf-mould and sand will be of considerable service. Lilies are by the botanist divided into five groups. In the group or sub-genus known as *Archelirion*, though consisting of very few species, are included *L. auratum*, *L. speciosum* and *L. tigrinum*, all of great value from a garden point of view. In dealing with garden Lilies, I will first of all mention

*LILIIUM AURATUM*, the golden-rayed Lily of Japan. This is decidedly erratic in its behaviour, and is in some cases very unsatisfactory where perhaps the season before, and under exactly the same conditions, it was all that could be desired. Various suggestions have at times been made to account for a habit this Lily has of suddenly dying off when apparently in good health. The cause seems difficult to determine, but whatever

it be, I have noticed that where the plants are growing in the open and fully exposed to the sun the greatest amount of mischief is to be noticed when heavy showers alternate with very bright sunshine. One of the most satisfactory modes of treatment is to associate it with *Rhododendrons*, as the soil and other particulars suitable for the *Rhododendrons* are favourable to this Lily, and the partial shade helps to ward off these attacks of sunstroke, if sunstroke it really is, that cause the deaths of so many. The huge clusters of massive blossoms as seen at Kew form a grand feature towards the latter part of the summer and early in the autumn, the interest in them being still further heightened by the individual differences to be found both in foliage and in flower. Two very distinct varieties of this Lily—*rubro-vittatum* or *cruentum*, and *virginale* or *Wittei*—are both very beautiful, but, as a rule, too delicate for the open border. Such, however, cannot be said of the variety *platyphyllum*, which is far more robust than the typical *L. auratum*. In the variety *platyphyllum* the stem is stouter, the leaves very much broader, while the flowers are larger and more saucer-shaped. It is really a grand Lily, and though we have not yet this year had any large importations from Japan, yet, as a rule, it can be purchased cheaply enough during the season.

*L. SPECIOSUM*, another of this class, will flower beautifully out of doors during the latter half of August and frequently for a long time after that. It is perfectly hardy, but is sometimes a little liable to die off suddenly after the manner of *L. auratum*, but not to anything like the same extent as that kind. The supplies of this Lily, of which numerous varieties can be obtained at a cheap rate in this country, are mainly drawn from two sources, viz., from Holland and Japan. From this latter country we get, as a rule, magnificent bulbs of richly coloured varieties, and also of that beautiful white form, *Krateri*. The varieties *roseum*, *rubrum*, *punctatum*, and *album* mostly come from Holland. The last mentioned, *album*, is totally distinct from the Japanese *Krateri*, the exterior of the flower being tinged with chocolate. Where herbaceous borders are maintained, a few good masses of this Lily in two or three distinct varieties form a very pleasing feature at a time when many of their associates are over, while bold clumps or beds, each consisting of only one variety, serve to show them to very great advantage. This is quite the poor man's Lily, and good examples may often be seen in cottage windows.

*L. TIGRINUM*, the last to mention of this section, is a very beautiful species, but as an ornamental plant the typical kind is greatly surpassed by the variety *splendens*. This particular form is generally very well done at Kew, and towards the end of last summer some large masses of it there were wonderfully effective. The double-flowered variety is very distinct and has some admirers, but most Lily lovers would, I think, prefer the single blossoms. It is, however, interesting as being the best example of a double-flowered Lily that we have in our gardens.

The sub-genus that contains the greatest number of species is that known as *Martagon*, the first example of which will be the species from whence this section has derived its name, viz.,

*LILIUM MARTAGON*, known also as the Turk's-cap Lily. The varieties of this species, though not particularly numerous, show as marked a divergence from each other as is to be found in any Lily, for first of all there is what is known as the common or purple *Martagon*, whose pretty little reflexed blossoms are of a dull purplish hue; then there is a variety with pure white flowers, and another, *dalmaticum*, which in some examples at least is one of the darkest of Lilies, the flowers being of a deep purple. The roots of these *Martagon* Lilies are very stout in proportion to the size of the bulbs and deep descending; hence they are more impatient of removal than most members of the genus. The first Lily of all to

flower in the open ground is one of the *Martagon* group, viz., *L. pyrenaicum*, with small yellowish green flowers, which have a very unpleasant smell; indeed, this feature is common to many other members of this section. Hence, though they are exceedingly graceful and the spikes of blossoms just the thing for large vases, yet they are not available for cutting owing to the heavy perfume, but as plants for the open garden some of the best Lilies are included among them. That known as the

SCARLET *MARTAGON* (*L. chalcedonicum*) is a very striking Lily, whose sealing-wax-like blossoms are at their best in July, at which time very few outdoor Lilies are in bloom. This also greatly resents removal, and very frequently the first season after being transplanted it will only throw up a puny shoot without any signs of flower. This latter remark will also apply with equal force to

*L. SZOVITZIANUM*, a very beautiful Lily with a plurality of names, as, besides that just mentioned, it is also known as *L. colchicum*, *L. ponticum*, *L. Loddigesianum* and *L. monadelphum*. The flowers of this are usually of a primrose-yellow, spotted more or less with brown, but there are a good many individual differences. This Lily succeeds best in a good, deep, loamy soil, but at the same time it must not be at all waterlogged. The Japanese

*L. HANSONI* is a particularly desirable member of the *Martagon* group, as in the first place it is less affected by removal than any of them, and the colour of its flowers—bright orange, spotted with brown—renders it very distinct. The petals are unusually thick in texture, looking almost as if formed of wax. *L. Hansonii* is especially remarkable from the fact that, with the exception of the *Madonna Lily* (*L. candidum*) and that beautiful hybrid raised there from, *L. testaceum*, it is the first of all Lilies to push up its delicate leaves in the spring. The common *Martagon* is, however, close on its heels. A small bed of *L. Hansonii* near the back of the Palm house at Kew was last season very striking, there being quite a forest of spikes, each carrying a number of pretty blossoms. That interesting hybrid raised between *L. Hansonii* and *L. dalmaticum*, known as *L. Dalmatiansii*, is just as amenable to cultivation as either of its parents.

*L. TESTACEUM*, just alluded to, is included in this group. The parents of this are *L. candidum* and *L. chalcedonicum*. The foliage is in general appearance about midway between the two, and much the same may be said of the flowers, their colour being a very pretty shade of nankeen. It is a vigorous Lily, flowering well in the open garden. Under the name of

*L. POMPONIUM VERUM* we have one of the brightest coloured of the early-flowering Turk's-cap Lilies. The leaves are very numerous, of a deep green, edged with white, and it is a Lily that will succeed even in stiff soils. The red form of *L. pyrenaicum* is often known as *L. pomponium*, hence the suffix *verum* to this greatly superior form. There are several species belonging to the *Martagon* group remarkable from their peculiar rhizome-like bulbs, and as a rule they need a certain amount of peat or leaf-mould in their soil. The roots of these are not particularly deep descending, and they require a fairly cool, moist spot; indeed, one species, *L. superbum* (known as the Swamp Lily), will succeed where the ground is quite moist. Two others belonging to this section are the Panther Lily (*L. pardalinum*) and *L. canadense*, both of which are very beautiful and variable in height and colour of the flower.

The Eulirion or tube-flowered group contains, among other species, *L. longiflorum*, one form of which, known as

*L. HARRISI*, is undoubtedly grown in larger quantities than any other Lily. This is, however, principally cultivated in pots under glass. From Japan, grand, well-ripened bulbs are now sent in considerable numbers, and they are the best of all the *longiflorum* section for planting in the

open garden, where they will flower beautifully in most seasons about the first half of July. A sandy loam suits this Lily well, and when the conditions are favourable it will increase at a rapid rate. Several of its immediate relatives are too tender or too fastidious in their cultural requirements to succeed as garden Lilies, but exception must be made at least in the case of two, viz., *L. Brownii* and the *Madonna Lily* (*L. candidum*). There seems to be an idea that *L. Brownii* is tender, but such is not the case, and its fine bold flowers, ivory white inside and pale chocolate on the exterior, are very beautiful. Of the *Madonna Lily*, so generally recognised as the type of beauty, little need be said.

After this come the cup-shaped Lilies, all of which belong to the sub-genus *Isolirion*, and though there are not many distinct species, yet the varieties are numerous. A good illustration of this is to be found in

*L. ELEGANS*, or *TUNBERGIANUM*, as it is often called. In this the flowers vary from the pale buff-yellow of *alutacum* to the deep blackish crimson of *Horsmanii*, through various intermediate shades. Besides these two, some of the best varieties are *pictum*, *Van Houttei*, *Alice Wilson*, *Prince of Orange*, *biligulatum*, *sanguineum*, *aurum marmoratum*, and *brevifolium*. All of the above are moderately cheap, except *Alice Wilson* and *Horsmanii*. A curious Lily is *L. elegans staminosum* or *flore-pleno*, as in this the interior of the flower is filled with flattened petaloid segments, thus forming a double blossom. While *L. elegans* belongs to the early-flowering Lilies, one variety—*venustum*, with apricot-coloured blossoms, very much like those of the Japanese *L. Batemanna*—does not bloom till all the rest are past.

*L. DAVURICUM* or *UMBELLATUM* is a larger and bolder Lily than *L. elegans*, and not nearly so variable in colour, for different shades of orange-red predominate in the case of *L. davuricum*.

*L. BULBIFERUM*, for which generally some seedling form of *L. davuricum* is made to do duty, may be distinguished by the bulbs in the axils of the leaves. The flowers of this are of a warm reddish orange. The last of this group to mention and nearly the last of them to flower is

*L. CROCUM*, which is too well known to need anything said in its favour. The members of this group of Lilies all do well in good sandy loam, and they may, as a rule, be depended upon to flower well the first season after planting.

Besides those above mentioned, the Himalayan *L. giganteum* is not nearly so particular as is generally supposed, while the charming *L. Henryi*, though of comparatively recent introduction and still far from cheap, has already proved itself to be a thoroughly good garden Lily. H. P.

## THE ROCK GARDEN.

### XVI.

#### AUTUMN FLOWERS.

SEPTEMBER has been a glorious month this year, and its warm temperature and brilliant sunshine gave to our favourite flowers in the rock garden a brightness quite unusual for these islands. Unfortunately these glorious colours did not last long, and were mostly destroyed by the sudden and premature cold weather experienced in October, and by the subsequent abundance of cold rains during November. It is during these autumn months that flowers in the rock garden are doubly welcome. In June and July we have hundreds of varieties of gay flowers to choose from, but not so when the year is on the wane and autumn tints and falling leaves show the approach of winter. Flowers in the rock garden that will last from September till the end of October, or even beginning of November, are comparatively scarce.

In the following notes I will enumerate such flowers as I have observed in bloom during the time mentioned, and, as in previous notes on the subject, I will divide the plants into dwarf rock plants, medium-sized plants, and tall plants.

#### DWARF ROCK PLANTS FLOWERING IN AUTUMN.

*Senecio leucophyllus* is one of the choicest and rarest rock plants. At Exeter it was still in bloom at the beginning of October. There it was planted in stony calcareous soil on the sunny side of a piece of rock. The plant was imported with several others from the Pyrenees, and represents the sole survivor. Plenty of sun and perfect drainage seem indispensable to its well-being. The plant is only a few inches in height; its leaves are pinnatifid and of silvery whiteness. The flowers are of a bright golden yellow, and though small individually they are very effective, as they are clustered together in a corymb of considerable size. *Omphalodes Luciliae* bloomed here during the last week in September. This is another choice plant which all too often, unfortunately, perishes quickly in the British climate, but probably the drought of last summer suited its requirements. There is something very charming in the delicate pale blue corolla raised above the glaucous leaves. It is a first-class gem, and altogether different from the weedy *Omphalodes verna*, which does so well when naturalised in woods or other half shady places. *Omphalodes Luciliae* perishes in the shade and requires the full sun. Another pretty rock plant which flowered here in September is *Frankenia laevis*. Though a British plant it is very seldom seen. It is an excellent rock plant, forming a very neat cushion of minute leaves close to the ground and numerous studded with bright rosy purple flowers. *Lippia repens* also bloomed in September in Devonshire. Owing to repeated failures with this plant I began to look on it as not being quite hardy in this country, but as it stood the severe test of last winter and is looking healthier than ever after the dry summer, I think the failures must be attributed to wet rather than cold. It forms a spreading carpet close to the ground, and its pale pink flowers are very freely produced, and show to special advantage if allowed to hang over a stone. *Epilobium obovatum* was severely cut last winter, but it has fully recovered, and in September was flowering for the second time. It is one of the most graceful things in the rock garden for a position in which its pendent shoots and crimson-purple flowers can show to advantage. *Dianthus alpinus* also has flowered a second, and in some cases a third, time this autumn, and its beauty can hardly be surpassed. *Cyclamen hederifolium* and other autumn-flowering kinds were blooming abundantly in September, and it is well known that they prefer a position at least partly shaded. Unlike most rock plants, they do not object to the shade of a tree or shrub, but, on the contrary, they prefer it. *Gnothera pumila*, with its dwarf habit and bright yellow flowers, was still in bloom on October 1. It seems to enjoy a sunny position and plenty of drainage. The same kind of position suits the beautiful white flowering *Antirrhinum glutinosum*, which during the last week of September was still in bloom. When planted so that its semi-pendent shoots can hang over a large stone this plant is specially effective. Among dwarf plants I will mention only two more, viz., *Arenaria purpurascens* (syn., *Alsine rubra*) and *Sisyrinchium bermudianum*. The former flowered in September (though its usual time of blooming is much earlier), and the latter

was still in flower during the second week of October, though the usual blooming time is June.

#### MEDIUM-SIZED ROCK PLANTS FLOWERING IN AUTUMN.

*Arnebia echioides* (the Prophet's Flower) was still in flower in October. It is always an object of great interest in the rock garden and of very easy cultivation, thriving perfectly well in ordinary loam mixed with a few stones. On account of its size it is suitable for the larger ledges of rocks away from the miniature plants in the select part of the rock garden. Its large yellow flowers are made additionally interesting by the five distinct black spots (according to the legend, the finger marks of the prophet). The vanishing of these spots is one of the mysteries of plant life not yet fully explained. Can it be that the mission of these spots is to attract insects which would effect fertilisation, and that the vanishing of the spots is a sign that that purpose has been accomplished? It would be interesting to hear the result of the experience of other correspondents who perhaps may have observed this natural phenomenon more closely. *Zauschneria californica* has during this season bloomed from September till November. All through October its bright scarlet flowers were as gay as possible. For dry positions, so isolated that the fast-spreading *Zauschneria* cannot imperil smaller plants, no more effective autumn display could be desired. The same might be said of the brilliant blue *Plumbago Larpentae*, an excellent companion to the former, which this autumn bloomed from the end of August till the beginning of October. Another most useful blue flower, though of less brilliancy than the last, is *Campanula Portenschlagiana major* (Paul's variety), also known under the names of *Campanula bavarica* and *Campanula mollis*. It is much larger than the ordinary *C. Portenschlagiana*, growing quite 10 inches high, and though it bloomed most profusely during June, it has produced a second lot of flowers, lasting all through September, so that it may well be counted among the autumn flowers. In my recent article in *THE GARDEN* on *Campanulas* I gave a full description of this variety under the name of *C. mollis*, but having, by the kindness of the Rev. Wolley-Dod, been furnished with the history of that variety, there can be no doubt that this *C. mollis* is identical with *C. Portenschlagiana major* (Paul's variety). A pure but paler blue is furnished by *Linum Lewisii*, which somewhat resembles *Linum alpinum*, but lasted in bloom till September, together with its congener, *Linum maritimum*, which latter, however, is distinguished by handsome yellow flowers.

Of late-blooming pink flowers on medium-sized plants I will mention only *Sedum populifolium*, which requires a sunny position, *Polygonum Brunonis*, which is an effective plant for a half-shady spot in the rougher parts of the rock garden, and the charming *Rhexia virginica*, which requires a moist and shady position. The last-named is seldom seen to perfection, but its rosy flowers with their yellow anthers are most attractive. At Newton Abbot *Rhexia virginica* was still in bloom on October 11, but the finest plants I ever saw I noticed last August in the natural bog garden at Oakwood, where batches covering a square yard or more were then just coming into bloom. *Saxifraga Fortunei* is a choice rock plant not seen so often as it deserves to be. It flowered in South Devon during the latter part of September, and flourishes best in a somewhat moist and shady position. The large glossy leaves are leathery

in appearance and have red stems, while the flowers are white.

#### TALL AUTUMN FLOWERS SUITABLE FOR THE ROCK GARDEN.

Tall plants can of course be admitted only here and there as small groups, or as isolated specimens where special effect is desired, or in the margin of shrubberies forming a distant background to the rock garden proper. *Gypsophila acutifolia*, with its elegant white flowers, lasted till September. The scarlet and purple *Lobelias*, such as *Lobelia cardinalis*, *L. fulgens*, *L. violacea* and the numerous sub-varieties, also last till September and are very rich in colour. On account of their somewhat stiff and rigid growth they are scarcely suitable for the rock garden when planted close together, or even as isolated specimens. When, however, they are so arranged as to form large, loose groups, of irregular appearance, with the plants kept sufficiently apart to allow the full development of some dwarf evergreen such as *Iberis*, *Campanulas*, or kindred kinds that would carpet the ground between the *Lobelias*, the effect is charming. Many types of the tall *Asters* or *Michaelmas Daisies* lasted till October, but all erect-growing, tall kinds should, I think, be banished from the close vicinity of the rock garden, where they would only mar the picturesque effect. But such kinds as *A. dumosus*, *A. Amellus bessarabicus*, *A. horizontalis*, and others of more graceful habit might with advantage help to enliven the background of rock gardens during a season when flowers are getting scarce. One of the most elegant late flowering tall plants, and admirably suited as a single specimen on a large rock, is *Desmodium penduliflorum*. When planted on a somewhat high elevation the full grace and beauty of the long semi-pendent branches, laden with an abundance of rosy purple flowers in large racemes, are shown to the best advantage. As a rule it does not commence to bloom until September, and its elegant and showy blossoms last till late in October or even beginning of November. *Salvia Pitcheri* with its handsome deep blue flowers is another valuable autumn plant which here in the west may often be seen in bloom in the open as late as November if severe frost has not set in before that time. Not quite so late is the blooming season of the handsome tall yellow *Thistle* (*Scolymus grandiflorus*), which lasted only till the beginning of September, but is a striking plant, deserving greater popularity than it enjoys at present. *Chelone obliqua* with purple flowers, and its white variety *C. o. alba*, lasted till the end of September, while the tall and handsome *Chelone barbata*, with its long tubular scarlet-ermson flowers, lasted here only till the beginning of September. Another red, though of a duller shade, is furnished by *Phygelius capensis*, which lasted throughout September, and grows about 2 feet to 2½ feet in height. Of about the same height are the bright yellow *Chrysocoma linosyris*, whose large corymbs of golden flowers last till the beginning of October, and the handsome *Senecio pulcher*, with large bright purple flowers, flowering till the middle of October.

Elmside, Exeter.

F. W. MEYER.

(To be continued.)

**Bunch Primroses.**—At the present time (December 3) I have a goodly number of plants growing in various positions, and those under a north wall are as free as those on a south border. During the last three or four weeks I have gathered two or three nice bunches weekly.—JOHN CROOK.

## APETHORPE.

AMONG the fine old houses of Northamptonshire, Apethorpe, the seat of the Earl of Westmoreland, is one of the best examples. It stands in the middle of a small park of not quite 200 acres, a little to the south of the equally ancient village. The house, like others of its kind, is built of and roofed with stone, and where the walls are seen in parts between the free growth of climbing plants, they bear the mark of age in their Lichen-stained surfaces. Apethorpe is of large extent, a house that has grown with the times, but always after the simple, beautiful style of its earliest parts, which date back to the time of Henry VI. The oldest part is that seen in the right-hand corner of the accompanying

characteristic of the district, with the park and its trees in the foreground, beyond its boundaries the public road, from which the house is seen to great advantage. The south side of the house looks out upon a lawn of velvety smoothness, rising slightly to the distant Yew hedges and Ivy-clad walls that separate it from the fruit and vegetable grounds beyond. The chief feature of attraction upon this lawn is two lines of Yew trees, two parallel hedges in fact, with a broad rectangular plot of Grass between, once an enclosure of some sort. Now and for many years the hedges have grown wild and the trees are of sufficient height to admit of the removal of their lower boughs on one side, which has been done, giving charming shaded walks beneath spreading branches on the inner side of both lines. A Lebanon Cedar on the lawn and quite near the house was once of considerable

men is now nearly 70 feet in height and its stem is about 12 feet round. There are also other thriving specimens of this tree, also of Thuja Lobbi, T. gigantea and other conifers. A plant of Salisburia adiantifolia is trained upon the walls of the house. It has a regular columnar stem 30 feet high, 1½ feet through at the base, and perfectly erect, whilst its thickness diminishes in a very slight degree in proportion to its height, the branches being trained out horizontally or in espalier form. The tree was probably planted soon after its introduction into this country, as Mr. Ewart said it was of large size when he came to the place, and might have been planted against the wall through lack of knowledge as to its hardiness.

The kitchen garden is surrounded and subdivided by fine walls and perfect Yew hedges, whilst the glass department consists of two

Apethorpe, Northampton. Engraved for THE GARDEN from a photograph by Mr. J. T. Hopwood, Bury Street, St. James', S.W.

illustration, whilst the large doors have evidently been at one time the chief entrance, no doubt later, when the house was extended round the four sides of the courtyard. The view here given is that of the courtyard, now a charming grass plot large enough for a tennis lawn, and with all the best rooms of the house looking out upon it, enclosing it on all sides. The archway seen to the left gives access to another spacious courtyard, round which are arranged the domestic offices. In the year 1603 James I., when on his way south to assume the crown of England, stayed at Apethorpe, and it was here he first met George Villiers, who afterwards became Duke of Buckingham.

The present entrance is on the east side, where a drive of fine breadth and graceful curve is margined with a broad sweep of turf that merges into the park, and the outlook is a pretty one,

height, but a storm rather more than thirty years ago broke asunder the main trunk at a height of about 30 feet. The lower and wide-spreading branches remained intact, and from these have started up a score or more of leading shoots as perfectly erect as though they were young growing trees. The tree is in the most perfect health; its main stem is over 20 feet round, and its branch-spread has a circumference of nearly 100 yards. On the south-west corner of the lawn are a few large flower beds and some long borders devoted mainly to hardy flowers, whilst the south-east corner merges into a group of conifers admirably placed at distances that permit of their unrestricted growth. The most conspicuous tree is a Wellingtonia, which Mr. Ewart, who has been gardener at Apethorpe over forty years, planted out of a pot in its present position in 1858. This speci-

vineries and two other houses that were gay with flowering plants at the time of our visit.

**The Glastonbury Hawthorn.**—A small standard tree of this early or winter-blooming variety is at the present time in full flower in the Botanic Gardens of Trinity College, Pembroke Road, Dublin. It was introduced several years ago direct from Glastonbury by desire of the Rev. J. W. Stubbs, D.D., who had seen this variety growing in the precincts of the abbey at Glastonbury when visiting that place some years ago. This tree has budded at Christmas-tide on several previous years, but it has never actually flowered during winter before this year. It flowered early in April of the present year and ripe fruits are now to be seen alongside the clusters of white flowers. The tradition or legend connected with the Glastonbury Thorn is well known. The original tree is said to have been

brought from the Holy Land as a walking staff by Joseph of Arimathea. On arriving at the site of the present abbey, he stuck his staff into the ground, where it budded and flourished as a living tree, astonishing the country people by flowering on old Christmas Day, which was held on what we now call Twelfth Day. When the change of style was made in the calendar of the Church, the people objected to it, and appealed to the non-flowering of the sacred Thorn tree as a natural protest against the new-fangled notions of time. This variety of Hawthorn is known as *Crataegus Oxyacantha* var. *præcox*, and was formerly much in repute amongst lovers of curiosities, but it is now rare in trade lists, and not at all common in gardens. It would be interesting to hear if it is now in blossom elsewhere in Ireland or in England at this inclement season of the year.—F. W. BUREIDGE.

## ORCHARD AND FRUIT GARDEN.

### RENOVATING VINE AND PEACH BORDERS.

WHERE Vines, Peaches, or similar fruit-bearing trees under glass are in an unsatisfactory condition or exhibiting indications of weakness, the present is a suitable season to take measures to improve the existing conditions by renewing the borders to some extent, and providing a better compost and more suitable root-run for the Vines or other occupants of the house. Provided the drainage is good, it is by no means necessary to make entirely new borders (in some cases no doubt it would be better to do so, but the expense deters many from such an undertaking), as much can be done by a judicious removal of a portion of the exhausted soil, replacing the same with a prepared compost containing such ingredients as will induce a fresh, active root action. The first step is to have the new compost all ready to wheel into the houses immediately it is required. There is always some delay, and if the weather is bad, still more time is lost; that is avoided by having everything ready to go on with beforehand. If possible, good fibrous turf from an old pasture should be procured, stacking it into a heap in the soil yard. A quantity of ashes from the burning of vegetable refuse, weeds, prunings, &c., is very desirable, taking care that all the wood is properly burned, otherwise fungoid growth might follow in the border. The ashes ought to be kept dry until required for use. If the natural soil is heavy and likely to set closely, a quantity of sharp sand will prove serviceable—such as accumulates at the bottom of a hill on the highway is first-class. Vine roots are especially fond of this sand, and will form a mass of fibre therein. Having chopped up the turf into fair-sized lumps and thrown out all the fine soil that may have been made in breaking up the lumps, add one barrowload of the ashes and one barrowload of sand to eight of the turf. If mortar or plaster refuse is available, a barrowload can be put with the above, or, failing that, two 10-inch pots full of bone meal can be added, thoroughly mixing the whole together and keeping it dry until wanted. My experience, again, when I took charge of the garden in my present situation may be useful to others similarly placed. I entered on my duties in the late autumn, and found the Vines, Peaches and Nectarines in a wretched condition, several eminent gardeners assuring me that I should have to root the whole lot out and make an entirely fresh start. Instead of following out the advice given, the Vines, &c., were cut well back

and the borders were gone over with forks and the soil removed down to the roots, a few of which were fully exposed, then raised and spread out on the sods of turf just as dug from the field. On the top of these roots a quantity of sand of the description mentioned was placed, completing the whole of the borders in the same form, *i. e.*, with a layer of turf, then a layer of sand about 1 inch thick, repeating the process until all was finished, at the same time making all as firm as possible. No other material was used, as the soil is naturally porous. The result exceeded all expectations. By the following autumn excellent short-jointed growth had been made, and the borders were, and have been ever since, one mass of roots. I have great faith in sand in moderate quantities for Vine borders; its usefulness can be seen if any alterations are made in the borders after its use by the quantity of fine fibrous roots that have spread amongst it. There may be little strength in sand, but if the gardener or amateur can manage to get plenty of roots to any sort of fruit-bearing tree or plant, it is a very simple matter to supply sufficient nourishment to meet all requirements. At the same time, it is never advisable to commence feeding until the roots have taken thorough possession of the soil. After renewing the borders in the mode indicated, a mulch of strawy manure will be ample for the first year, and this mulch is not recommended for its fertilising powers, but simply as a check to the growth of weeds and grass that would otherwise spring up, and thus reduce the fertility of the borders.

W. G. C.

**Forelle or Trout Pear.**—This handsome Pear is always greatly admired when in good form, but frequently its handsome appearance is its best recommendation, especially if grown against a wall. No doubt the largest and best coloured samples are obtained from wall trees, but my experience is that they are always the worst in quality. I have tasted Forelle from wall trees in gardens widely apart and under very dissimilar conditions always with the inferior flavour very much to the fore. On the other hand, there is a marked difference in favour of the fruit from standard trees. Though naturally smaller and with less colour, the quality in every instance has been infinitely superior, so much better in fact that the variety would not be recognised by most gardeners who had not tasted it under the two different forms of growth. I think Forelle not worth its room on a wall, fairly good on bush trees, and very good on standards, on which excellent crops are produced if the trees are on good land and well manured annually.—G. C. R.

**Pear Marie Guisse.**—We are often told that more late Pears should be grown, and amongst various sorts recommended Marie Guisse is described as a valuable variety fit for use in March, with several other good qualities. After growing Marie Guisse as a bush, wall, and cordon tree in quantity for about eleven years, I consider it one of the most unsatisfactory Pears I know. Every year the trees bloom most profusely, make excellent growth, and appear all that could be desired as trees, but they very seldom bear even a quarter of a crop, and if they bore freely, the fruit is too small and poor in appearance to be of any market value. Manuring with chemical fertilisers suited to the soil and crop brings about very little improvement. Lime was recommended by a leading grower as a sure remedy for its shy-bearing, but all efforts in the way of improvement have failed.—W. R. H.

**Mulching Raspberries.**—This is often performed at the wrong season of the year. Many wait till spring, when the soil between the rows on stiff land is wet and cold from the winter rains. They then dig in a quantity of cold spit manure, mangling all the best surface roots, which every

practical gardener well knows are the best. True, fair crops of fruit are produced even under this system and when the canes are crowded round stakes in the old-fashioned way, but the fruit is small and flavourless compared with that produced from canes rooting near the surface and trained to wires fixed to posts. I get the best results from thinning out all the old fruiting canes early in autumn, raking off the stale unused mulching, giving a good broadcast sprinkling of artificial manure and re-mulching with spent refuse from old hot-beds. Into this the new roots rush readily, and medium-sized fruitful canes are produced that will stand severe frost.—J. C.

**Packing fruit trees.**—I cannot help thinking that insufficient care is taken in packing fruit trees for despatching long distances, even by some of the noted fruit-growing firms. As a rule, the trees are laid in in perfectly dry straw without a vestige of damp material about the roots, the result being that on arrival at their destination they present a parched and dried appearance; and I know from experience that many of the fibrous roots are injured beyond recovery by this rough-and-ready treatment. When fruit trees are sold in market towns at a cheap rate one cannot expect any extra trouble to be taken with them, but surely firms who have a reputation to keep up would do well to spend a little time in enveloping the roots of each consignment in a little damp hay or strawy litter. I have been so much annoyed by the non-observance of this common-sense rule, that I now make a stipulation that moist material is to be used.—C. H. N.

**Pruning Apple trees.**—There has been a great deal of discussion lately in THE GARDEN on the pruning of Apple trees, so I am sending by this post two photographs of Blenheim Orange Apple trees, showing how fruitful this variety is here with close pruning. I have pruned the trees for sixteen years and they have only failed once in that time to give crops of good fruit. The trees are now 7 feet high, and have been planted twenty-eight years.—THOMAS GOLDRING, *Chilgrove, Chichester.*

\* \* They seem healthy and well-laden trees, but probably large, fully grown trees would under other conditions be equally valuable.—ED.

**Morello Cherries.**—To "A. W.'s" advice to grow Morello Cherries as bush trees rather than on north walls, the obvious reply is that fruits on bush trees are seldom so fine as those produced on wall trees. So richly coloured, fleshy, and almost sweet do these fruits become on walls, that they are sometimes used for dessert and much liked. But I find it difficult to understand how it is that bush Cherries as advised to be grown should become so infested with aphids and need so much cleansing, whilst these same Cherries grown as standards do well, fruit well, and never seem troubled by insect pests. That is at least my experience, for near to where I lived in Middlesex there were growing and still are there scores of standard trees, some thirty years planted, that seemed to be always in good health, always clean, always carried good crops of fruit, and certainly never did get any cleansing. I know so much cannot be said of bushes. But, apart from this circumstance, is it not better to grow this Cherry as a standard than to occupy with it valuable space in gardens as bushes? There is no fruit tree, not even an ornamental Crab, that furnishes more beauty as a standard than does a Morello Cherry. It is a beautiful lawn tree. The head is never unduly large and is always naturally of drooping form. When in bloom the trees are masses of snow-white flowers, and when in fruit in the summer are rich with colour. Birds seem very chary of attacking the fruits. In the neighbourhood of the market orchard referred to they were numerous, but the grower always gathered his fruit fully ripe and sound. Even if birds did have some of the fruits, might such feeding not keep them from doing harm elsewhere? Trees on walls not only can be very easily protected, but the fruits can be preserved on them far longer than could be the case with bush trees.—A. D.

**RIHA'S CORELESS PEAR.**

The principal merit of this new variety consists in the perfect absence of the core, there being

skin, which is more or less covered with fine dots of a delicate cinnamon-coloured russet. The flesh is white, tender and melting, very

of October, and if carefully treated will keep to the middle of December. The tree is a very good grower and an abundant bearer. Taking it altogether, this new variety highly deserves to be classed among the best of autumn Pears.

Berlin. L. SPATH.

Riha's Coreless Pear.

**Plum growing.** — The successful Plum tree, says Mr. S. D. Willard in the *Rural New Yorker*, is one of moderate growth in the nursery, on a soil that has not been over-stimulated for its production, has been planted with care, cultivated and grown intelligently by a man of sufficient liberality to bestow upon it the same liberal treatment that would be given to a thoroughbred animal—i.e., protected, cared for, and fed with consideration up to such time as a bounteous crop of fruit may have matured ready for harvesting. This should be picked and handled carefully, in baskets provided especially for this purpose, and in them transferred to the packing house or barn, where it should be assorted and graded carefully as regards size and quality, all being so nicely done that the producer would feel proud to have his name appear upon the package to whatever market it might be shipped. The product thus handled, finding its way into the hands of an honest city commission man, will furnish convincing proof of the fact that there are successful Plum trees. Plums and Currants make a good fruit team, but it must be remembered that both require the best of care.

**Apple Red Astrachan.**

—How very seldom we see this Apple mentioned, the reason probably being that few can give it a good name. So far as the individual fruit of Astrachan goes, there is no fault to find with it, but its great drawback lies in the tree refusing to bear, and this in spite not only of rigid root-prunings, but also of lifting and removal to fresh quarters. It is not that the tree makes extra strong wood, as in my case it is only of medium thickness and is tolerably well furnished with spurs, but the latter are minus bloom buds. The few fruit the tree under my charge has borne was produced on shoots about 6 in. long. This fact led me to think that, like Irish Peach and Worcester Pearmain, this was its natural way of fruiting, but although all the short, sturdy growths have been left at the summer pinching, no more fruit has been secured. I may add that I have only had experi-

only some feeble marks of it left, combined with a first-rate quality. It is a large pear-shaped or conical fruit with a greenish yellow

juicy, sweet, with a rich flavour. It will no doubt prove a valuable Pear for canning. It ripens in November and sometimes at the end

ence with it on a wall and espalier. Perhaps some reader of THE GARDEN can speak of it as an orchard tree.—J. C.

## EXHIBITING PEARS.

A VERY proper and needful plea is that put in so forcibly by Mr. Parker in favour of stewing Pears. Our methods of judging Pears at shows very forcibly illustrate the readiness we have to run after appearance instead of quality. Many Pears to which prizes have been awarded at autumn exhibitions would, if cut open, show that, in spite of apparent solidity and fitness, the germs of decay are already apparent in and about the core, and that the end of these fine fruits was near. Stewing Pears, such as Uvedale's St. Germain, Catillac, Gen. Todtleben, and Vicar of Winkfield, will, as a rule, keep long and sound, the two first especially. They may be used at any time from their first gathering to the latest in the season, and in a properly cooked condition make the most delicious of fruit that is conceivable. Dessert Pears may not be used till ripe, and when ripe their days of usefulness are indeed few. Even when had, how many are but soft, buttery pulp with little flavour, whilst stewing brings from out these large hard, enduring varieties the subtlest and richest of flavour that cooked fruits will give. Why, then, are not stewing Pears, if of good size and relatively handsome, not to be regarded as in every sense as worthy of consideration in collections as are any other varieties? Where there are no special classes for them, judges should be instructed to favour the presence of one or two dishes in collections, according to numbers. That is a degree of recognition which every gardener will admit they are entitled to because of their exceeding usefulness. In ordinary Pears, where stewing varieties are not shown, I note that judges invariably go for ripeness, even though that element is not specified. I cannot understand why that feature should be required wholly. What can be more unfortunate in relation to dessert Pears than having half a dozen varieties, perhaps all good, yet ripening off at the same moment; what waste inevitably results? Would it not be far better were judges to require in a collection of, say, six dishes, that these should follow each other in maturing, and that all varieties ripening at once should be regarded as undesirable? If Clapp's Favourite and Marie Louise be associated with Doyenné du Comice and Glou Morceau, with perhaps a couple of others intermediate in ripening, even though some be quite green and hard, yet well-grown, would not such a collection be much more worthy of an award than one in which all the fruits were ripe, perhaps over-ripe? Collections of Pears shown for flavour alone are more difficult to obtain, because, to test flavour, all must be ripe at once. One, or at the most two varieties shown specially for flavour are sufficient at a show, because any good selection of best flavoured sorts should have a long ripening range. It would never do, however, to take flavour in any shown variety for granted, whatsoever may be its reputation. Pears are somewhat uncertain in quality, varying very much according to soil, situation, stock, or manner in which grown. For that reason judges would have to taste one fruit at least from each dish. I am not sure whether, in the case of all dessert Pears, it would not be a good plan to cut one fruit from each dish right through the centre, to test condition, as fresh handsome-looking samples may often under such tests prove to be either in a state of premature decay, or gritty. Tests of this sort, if strictly applied, might in time do much towards creating higher requirements as to the eating qualities of Pears.

A. D.

**Black fly on Peach trees.**—At page 434 the question is asked how to destroy this pest on

Peach trees. "W. I." in his reply is certainly too daring in his recommendation to use petroleum for syringing the trees. Few gardeners would ever attempt it at this season of the year, no matter how well it was mixed up. What "W. I." recommends in the remainder of his article is certainly better, but for the sake of a little more time it would be equally as successful and no risks would be run in injuring the buds, which must certainly be the case if syringed, by going over the old wood and between the buds carefully with the solution recommended. I would advise "Subscriber" by all means not to syringe his trees. I do not say it without reason, for some six years ago I saw a house of Peaches which received such a check, that complete failure resulted the following year. Should "Subscriber's" trees be infested again next summer by this pest, let him syringe his trees well in the afternoons, and then go over the shoots affected with some good tobacco powder, using a distributor or puff to do so. If this is done when the foliage is wet and continued for a week or fortnight, he will soon rid them of black fly. The great secret of success in Peach culture can be summed up in a few words: Extreme cleanliness, good loam, and plenty of water at the roots, keeping the foliage thoroughly (not half) syringed at least once or twice a day. It is from neglecting the latter that so many failures arise with Peaches.—GEO. BURROWS, *Berwick Gardens, Shrewsbury.*

**Grape White Tokay.**—This Grape is by some described as a coarse one, but this condition generally arises from the Vine being grown in too little heat. If grown in an ordinary cool vinery and started late, the berries never assume anything but a greenish white tint, and the flesh is then decidedly coarse. When favoured with a Muscat temperature, however, and ripened by the first week in September, White Tokay is a Grape of no mean order. It will hang in a plump condition long after the Muscates in the majority of gardens have shrivelled. The Vine has a good constitution and crops best when growing in soil the reverse of rich. This last condition is necessary in the case of all the large late varieties of white Grapes such as White Nice, Trebbiano and Syrian. A shallow border composed of a medium loam, with a large percentage of mortar rubble, produces a hard lateral growth, which ripens early and well, and is the only remedy against barren laterals, so common in these varieties. Some of the finest bunches of this Grape I have seen for a long time were hanging last September in a lean-to vinery at Rackheath Park, near Norwich.—J. C.

## PRUNING PEACH TREES IN THE OPEN.

MR. YOUNG, Mr. Clarke and other advocates of early pruning will readily admit that the practice is not general. The finest Peaches ever seen by me on open walls have been from trees pruned late in the spring, after they were coloured over with the opening bloom. In healthy trees there is no serious loss of vital force or sap through this late pruning. No doubt gross or imperfectly ripened Peach wood is the first to fall a prey to frost or severe cold. But cold by no means selects all its victims from unripened shoots and branches; there are others—and far more numerous and valuable ones—that may be saved or lost through our time of pruning. In general terms, prune Peaches in the open air early; they will grow and blossom earlier—in the ratio of the date of their pruning—atmospheric conditions, site and soil being equal. This very potent fact in the production of fine Peaches in the open air seems wholly left out of the reckoning by Mr. A. Young. The late pruner secures a later bloom than the early pruner, and in our capricious climate a week or a fortnight's difference in the season of blooming often makes all the difference between food for frost and luscious melting Peaches for table or profit. Until Peach blooms open they are virtually safe in our climate. Hence every hour, day and week we can defer the blooming period by late pruning and other expedients, we increase our

chances of a full crop of Peaches and Nectarines from the open wall. This is less a matter of theory but of fact demonstrated in different counties and gardens for years. I know of few things more likely to arrest the rising popularity of Peach growing in the open air than the declaration that the time of their final pruning is immaterial, or rather that the earlier the trees are pruned after the fall of the leaf the better. To this I advise the direct opposite. The later the spring pruning the later the blossoming, and the surer and more certain the crops. I have hinted at other methods of retarding the blossoming of Peaches in the opening besides that of late pruning. One of the simplest and most potential is the unnauling of the trees early in the autumn, gathering the branches into loose bunches, and wintering them, as far as safety and convenience admit of, from the wall surface with all its incessant alternations of temperature and enervating effects on the shoots backed so closely against the bricks. A few stout stakes thrust in a foot or more from the wall surface to which the trees can be fixed in sections will enable Peach growers in the open to combine two things essential to the highest success, viz., the uniform maturity of all the fruit-bearing wood and the retarding of its blossoming until the latest possible moment. D. T. F.

**Apple Winter Peach.**—It would be interesting to hear something as to the quality of this this year. As a rule it may be termed good in this part of the west of England, but this season it is very poor indeed and unfit for dessert. I never had such a good crop or such fine fruit, and was rather proud of the extra large and beautiful fruit, but on testing some before sending them in for dessert, the flavour was so wretched that all will go to the kitchen for cooking. The tree is a free bearer, the fruit large for dessert, very pale in colour, sometimes flushed on the sunny side, and keeps well until February.—W. R. H.

**Apple Cathlin Pippin.**—I am frequently requested to give a list of small dessert Apples that will keep well into the spring. A really good, but comparatively little-known variety for this purpose is Cathlin Pippin, which is occasionally seen at some of the fruit exhibitions, where it always attracts attention by its very distinct bronze colour. The flavour is very distinct and rich, and at its best during the first two months of the year, though occasionally it is excellent in March and April. Worked on the free stock, it has not cropped very freely, but on the Paradise stock the produce has been heavy and continuous. Those who desire a pretty and delicious little dessert Apple at the period mentioned will find this variety satisfactory.—W. G. C.

**Unnauling Peach trees.**—The practice of unnauling Peach trees on open walls in December or January is a very old one, but I think there is greater need for practising it now-a-days than formerly, when our winters were colder and more uniform. Those only who have had experience with open-air Peach trees know what excitable subjects they are, and, strange though it may seem, the more immature the wood is, the quicker the trees start in mild springs. This is doubtless partly accounted for by the fact that the roots of Plum stocks, on which most Peach trees are worked, are never quite dormant, even in mid-winter, young quill-like roots being often discovered when lifting trees at that date. The chief reason for unfastening Peach trees is to bring the bearing shoots away from the bricks, which sometimes become warm from the sun's rays even in January and cause the buds to expand.—C. C. H.

**The winter moth.**—So far as my experience has gone, the winter moth commits most harm on standard trees and where standing thickly. Where individual trees are, the harm relatively has been materially less. By far the worst form of depredation has been seen in large orchards, where several acres of trees have been stripped of every leaf. That form of defoliation is, however, rare even where, as in Middlesex, for instance,

orchards of standard trees are thick and old, yet not only is nothing done to check or prevent the access of the female moth to the trees by the aid of grease bands, but very little indeed is known of the remedy. Only a few days since, talking to an old fruit grower there, he regarded the information given on this head as something absolutely new. That fact illustrates the immense difficulty there is in getting practical information into the heads of men who hold to ancient ways. But seeing that modern fruit culture, so far especially as Apples are concerned, now centres largely on bush trees which seldom have any clean single stem round which to fix a grease band, it would be interesting to learn whether "W. G. C." or any others who have had experience of such trees and the winter moth any such bands can be utilised successfully in their case. Perhaps it may be said that because bush trees are readily accessible, the clusters of eggs or the live caterpillars may be gathered ere much harm is done, or the trees can be effectively sprayed. That is so, of course, but if the grease band can play no useful part in their case, then, as regards them, the applying of grease bands is more difficult than in the case of standard trees. Do not constant stirring and frequent manuring of the soil about trees, especially where they are not too densely planted, do very much to counteract moth attacks?—A. D.

#### APPLES FOR KEEPING.

IN looking over the stock of these towards Christmas one is inclined to ask the question, where are those huge specimens that occupied the shelves some time ago? Fortunately, however, there are others still remaining that remind us of the past, and amongst these may be mentioned Lane's Prince Albert. This Apple is as sound now as when gathered from the trees, and though it does not possess that enticing colour to be found in some others, it is nevertheless one of the best that we have, taking it all round. Hanwell Souring will compare favourably with many others, though perhaps the name is against it. The fruit of this variety is unusually fine this season and with a brighter colour than I have ever seen, although the crop was a heavy one. To my mind this should be classed amongst the best keeping Apples we have. It certainly is one of the most reliable for cropping, for during the last eighteen years the trees have never failed to bear a crop, though in some seasons the yield is heavier than others. Wellington is again first-class and should occupy a place in every garden. Baumann's Red Reinette is another that will no doubt become very popular. It is a good cropper, the fruit of splendid colour, and appears to keep well, for it is as sound now as when gathered. Hambleton Deux Ans is certainly one of the best long-keeping Apples we have, and at the same time a good cooker. This variety is much grown in some of the midland counties, and where it does well there is not a more profitable Apple to be found. I remember seeing a tree at Oaken, in Staffordshire, that bore thirty bushels of marketable fruit one season. Then again there is that good old variety Afriston. The finest lot of fruit I ever saw of this was grown about three miles north of Chesterfield, in Derbyshire. There was not a single specimen amongst them that would not have turned the scales at half a pound. It was raised in the adjoining village to this many years ago, and though on stiff cold soil the trees are apt to canker, it is nevertheless well worthy of a place in all gardens. Yorkshire Greening is also one of those that ought to command a place in our orchards, for though the tree has a somewhat rambling habit, it may be kept within bounds without undue pruning. With me this has never failed to produce a crop, and as it keeps sound till February, it may be classed as a late variety. Norfolk Beaufin may not be one of the most prolific, but it is certainly one of the best keepers we have, and on that account should be accorded a place in every private collection. The fruit this season is of exceptionally fine quality, and carrying more

than an ordinary amount of that bronzy colour so peculiar to this variety. Neither should we by any means neglect to plant such old favourites as Northern Greening and Easter Pippin, for though there may be others with a more showy appearance there are certainly none that are more useful in the kitchen during April and the early part of May. We are too apt to plant Apples and Pears for their fine appearance, but it should be remembered that fine fruit in October and November will not prevent the cook from complaining after Christmas if there be no supplies forthcoming. Horticultural societies have done well to encourage the growth of fruit, but they would certainly do a very great service if they would encourage the production of long-keeping varieties of Apples and Pears and appliances for their preservation. It has for some time been known that such plants as Lily of the Valley and many of our hardy early spring flowers may be kept back in order that their blooms may be made to expand in the autumn months. Why should not our fruit rooms be fitted with appliances whereby they may be kept cool enough to prevent the supplies from premature decay, and so prolong the season till other fruits are ready for use. Most gardeners know that April and the early part of May are the two worst months in the year to furnish the kitchen with a change of fruit for tarts, etc., but if by means of appliances similar to those used for retarding the growth of plants, they could preserve fruit, there would be no difficulty experienced in this respect. We all know the advantage of a cool cellar in summer, how that many tender fruits, such as Peaches and Melons for example, may be preserved for several days if taken into them before fully ripe. We seem to have overcome the difficulty of importing soft fruits by such means provided the journey is not too long, then why should not we be able to preserve our own productions in the same way? We complain much about foreign competition, yet when we have an abundant supply of home-grown fruit it seems to go begging, while that from distant lands commands the market, whereas if the former was properly husbanded there is no reason why it should not find most favour. H. C. P.

*Uckfield.*

#### SHORT NOTES.—FRUIT.

**Coe's Late Red Plum.**—This is a wonderful cropper, and keeps a long time. I have some still fit for kitchen (December 5) from a tree growing on the front trellis of an orchard house.—JOHN CROOK, *Forde Abbey.*

**Plum Dymock Red.**—This dark red Plum is extensively grown in the Dymock district of Gloucestershire, and is considered one of the best and most reliable market varieties grown. Perhaps some reader who has grown it and Smith's Purple Prolific will state if they consider the two distinct. Grown under similar conditions, I am unable to detect any difference.—W. G. C.

#### FERNS.

##### ADIANTUMS IN WINTER.

MOST of the Adiantums require some care to keep them in good condition throughout the winter. Those which are required to give cut fronds and those to be used for decoration will need careful management to keep up a regular supply. It is easy enough to keep up a good supply up to Christmas, but it is during the first two months of the year that the supply often falls short. To provide against this, some plants should be kept in cool frames during the summer, and then taken into warmth early in the autumn. The plants will then get a fresh start and make good fronds, which will mature and keep fresh until those that make their spring growth are ready for use. Many of the Adiantums will continue under favourable con-

ditions to make growth throughout the winter, but most of the cuneatum type are better of a rest. Such plants as are not likely to be wanted until late in the spring should be kept cool and moderately dry during the autumn; they will then start away freely if given a little more warmth early in the year. Where the pots are well filled with roots, a little liquid manure or a slight sprinkling of any of the artificial fertilisers will be very beneficial at this period.

In growing on Adiantums for cutting those that have well filled the pots with roots will be found to make the best fronds; they should be grown as fully exposed to the light as possible, and should not be crowded together. More good fronds will be obtained from a less number of plants where they have plenty of room. Although those of the cuneatum type do not require a high temperature, a sudden change is sure to prove disastrous. Such as have been gradually hardened off after the fronds are well matured will not suffer unless actually frozen, but if taken from a high temperature, a slight exposure to cold will cause them to turn black. This will not show immediately. It may be some days if kept in a cool house, but if put into heat they will very quickly change colour. I find *Adiantum elegans* is much harder than cuneatum, and makes growth in winter better than the old favourite. *A. elegans* also makes rather larger fronds, and though it is doubtful if it will ever entirely supersede the old Maiden-hair, it is certainly more useful for some purposes. Of large-fronded sorts which may be recommended either for cutting or as plants for decoration, *A. Colissi* is one of the best; the large spreading fronds have medium-sized pinnules, and these are somewhat distant, giving it a very light appearance. A scutum is another valuable Maiden-hair, as it stands well either as a pot plant or when cut. *A. Williamsi* will be found to be of great service in winter; one drawback, however, is that the pinnules drop off, especially from the older fronds. It is remarkable that this distinct *Adiantum*, though it appears to produce good spores freely, is very difficult of increase. It may, however, be easily propagated by dividing the rhizomes. H.

#### THE CLIMATE OF THE ISLE OF WIGHT.

I THINK that we may feel greatly consoled by the comparatively little injury which the most severe season we are ever likely to have was able to bring upon us. Nor is this an opinion which I am singular in holding. Some two or three months ago I paid a visit to Major Gaisford, at Otlington, near Worthing, whose interest in matters of this sort is very great indeed, and his knowledge is on a par with his experience. It may be doubted whether there is any garden in the whole kingdom which is more noticeable than his for rare and beautiful shrubs. He has somewhere about seven hundred specimens of the very best sorts that can be procured, which have been gathered together with great skill from all parts of the world, and at much expense and trouble. Now, what struck Major Gaisford more than anything else about last winter was this—the comparatively little harm it did his trees. I think he said that he had not lost outright more than four or five per cent. of his very valuable collection, which, of course, means that he has only some thirty or thirty-five gaps out of seven hundred ornamental trees and shrubs which he possessed. Can anybody weep over that and not rather say that it is a very striking fact, and one that all gardeners should be ready to take to heart? Of course, a great many more than thirty or thirty-five specimens were knocked about and rather mauled by the cold, but this only implies in very many

cases the loss of one season for blossom, and it may be forty or forty-five years before such an ordeal comes upon us again. At any rate, that length of time has elapsed since we passed through the like. Now, what applies to Worthing, applies *a fortiori* to the Isle of Wight. I am not comparing my garden with that of Major Gaisford, for it would be very foolish to do so, but I can see from looking at his things and my own that, good as the climate of Worthing is for vegetation in general, that of the Island is better. At any rate, I would not exchange climate for climate and soil for soil. A loss, therefore, of only four or five per cent. of rare and valuable shrubs in a winter like that of 1894-95 should invite gardeners to be more enterprising, more trustful, more given to make experiments than is generally the case. I do not believe that in my own garden I have lost more than one or two shrubs and trees from the effects of the cold, and I mourn over *Acacia dealbata* and *Eucryphia pinnatifida* more than anything else. And when we speak of losses, let us not be slow to bear in mind survivals as well. Some persons so exclusively fix their minds on some two or three things which have slipped through their fingers that they forget altogether to register what may now be called safe beyond all doubt. For here is the good which a severe winter has done for us. It draws the line of safety in the clearest possible manner, and we may calculate that anything that is alive now has not much to fear in the future, unless one thing happens which it must be left to time to reveal. It must be admitted, of course, that if we are to have a cycle of winters like the last, and they are to come on us one after the other in very rapid succession, then trees and shrubs will go down in large numbers around us, for they will feel the second winter more than the first, and the third more than the second, and so on, and no one could say how bare and naked we shall be if this sort of thing is to continue. "But sufficient for the day is the evil thereof," and, so far as our own lives tell, an ordeal like that we are suffering from is only to be expected once in about forty or forty-five years. This is what the past says to us, and, of course, if the future is to be unlike the past we can draw no conclusions whatever, but if things are to be as things have been in recent years, we may be comforted and not discouraged by what we have met with of late. Here in my garden it is now a matter of perfect certainty, unless we have a new dispensation, that such a magnificent climber as *Mandevilla suaveolens*, which is generally grown in a greenhouse, will live and do well in the open air in the Isle of Wight. Here also a shrub from Mendoza, in South America (*Poinciana Gillesii*), which is grown in a pot in the temperate house at Kew, and does little there, but whose beauty, alike for foliage and for blossom, cannot be exaggerated, did perfectly well. It is now about 20 feet high, and it seemed to quite laugh at the very worst an English winter could do for it. No one had thought of such an occurrence, but anyone can see it when in bloom by passing through my gates. And so with many other things. Camellias have proved themselves to be much more hardy than Laurels, and shrub after shrub is now bearing witness to this. On the whole, therefore, what has been saved from last winter speaks much more loudly to us than what has been lost. There is no saying what the Isle of Wight can accommodate, because it has never been properly tried, but if any conclusions are to be drawn from the winter of 1894-95, either at Worthing or here, they are immeasurably on the side of encouragement, and there is nothing to deter us—certainly nothing to deter any gardener from widening his field of work, and from trusting he may succeed with a

large number of trees and shrubs of a most ornamental description if he only gives them a chance. —HENRY EWBANK, in the *Isle of Wight Observer*.

## GARDEN FLORA.

### PLATE 1046

#### THE CROWFOOTS.

(WITH A COLOURED PLATE OF *RANUNCULUS LINGUA* \*)

THE Crowfoots, to which the subject of the coloured illustration belongs, are very important in the hardy flower garden, where free-flowering plants are always welcome. From the early spring-time until late autumn the beds and borders are in a large measure indebted to one or more of the many species of this remarkable genus. The alpine meadows, almost on the verge of perpetual snow, are carpeted with their large white and yellow cups, the valleys are also brightened with their golden flowers, and even the watercourses remind one,

as our much-admired mixed borders and a great deal less troublesome. *R. Lingua* and most of its allies may be increased freely by division or seed.—D. DEWAR, *Botanic Gardens, Glasgow*.

— The genus *Ranunculus* is a very large and comprehensive one, and, in common with other large genera, it contains many species that to the gardener are worthless, while many others deservedly figure among the choicest and most valued plants of the garden. Regarded as a whole, while inhabiting a somewhat wide area, the majority may be said to be of quite easy culture and amenable to our English climate. This is even true of the many choice alpine kinds, which in reality are the gems of this genus, and include some of the rarer species that are none too plentiful at the present time. For the sake of convenience, for reference, and more particularly for dealing with the cultural requirements of the species, I have roughly grouped them under distinct heads in the following order: 1, moisture-loving; 2, alpine; 3, herbaceous; and 4, florists' kinds. The first group has its representative in the accompanying

The Rockwood Lily (*Ranunculus Lyalli*).

as evening falls, of a fairy garden, the large, bright yellow cups of *R. Lingua* helping to keep up the illusion. *R. Lingua* is a semi aquatic species and a native of Britain. It should be largely planted wherever it does not occur naturally. It requires very little care to thoroughly establish it, although well repaying any extra trouble taken with it. In shallow water never more than a foot in depth at most it will be found quite at home, and even on the edges of large watercourses or lakes it may be established with fine effect. Its large handsome flowers are a welcome change to what is too often a dreary waste. It grows in great abundance on the banks of the historic Kelvin.

On the margins of ponds or rivers it may be intermixed with such as *R. acuminatus* and the better forms of *R. acris*, as also the nearly allied Marsh Marigold (*Caltha palustris*) and the various species of Globe Flowers, all of which are showy and suitable for such positions. Indeed, there is no reason why a large and beautifully natural flower garden should not be made on the water edge as charming and interesting

\* Drawn for THE GARDEN at Gravetye Manor by H. G. Moon. Lithographed and printed by Guillaume Severens.

plate; the second includes those, mostly of dwarf habit, from the higher mountain-ranges, such as *glacialis*, *alpestris*, &c.; the third, those of taller growth, that renders them more suitable for the herbaceous border; while the fourth embraces all those varieties which have had their origin in *R. asiaticus*, and which now play an important part in the embellishment of our gardens in spring and early summer.

#### MOISTURE LOVING SPECIES.

*RANUNCULUS AQUATILIS*.—This, perhaps one of the prettiest of our aquatic weeds, is found in abundance in many parts of Britain—in ponds, or on wet, marshy ground. The broad sheets of its pure white blossoms are very effective in the full sunlight. It spreads rapidly, however, and when introduced into small areas will have to be kept within bounds. The plant flowers profusely for three or four months, usually beginning about the middle of May.

*R. LINGUA* (the greater Spear-wort).—This is also a native of Britain, but by no means so common as the last-named species. It is not too much to say that it is among the handsomest of water-side plants, delighting to send down its dense fibrous roots into the wet, loamy soil usually found in our English marshes. The flowers are nearly or quite 2 inches across, yellow, and, as

will be seen by the accompanying plate, are produced in profusion. In heavy soil at the margin of the lake or pond the plant grows quite freely, the flower-stems rising to 2 feet or 3 feet high

Florists' *Ranunculus*.

The plant is deserving of more attention, as we have none too many of these summer-flowering aquatics. I say aquatic (even though the plant is strictly a water-side plant) because it may be grown in pots, pans or baskets in loamy soil if partly submerged. And in this way the artificial pond in the rock garden or similar place may have its share in the summer of this beautiful plant. The artist has given us in the plate a genuine bit of Nature by his happy association of the Water Forget-me-not (*Myosotis palustris*) with the *Ranunculus* in question, as pleasing as it is real. The two are perfectly happy together, making a very charming picture when seen in good condition.

*R. LYALLI* (Rockwood Lily).—This is also called the New Zealand Water Lily; but, call it what we may, there is only one opinion concerning the plant, viz., that it is at once the grandest and noblest of its race. It is this in its every aspect—its foliage, its flowers, its great height, in all these a giant indeed. On its introduction doubts were entertained concerning its hardiness, but these are gradually being dispelled. At Kew a plant has stood out for two seasons, but I am not sure whether it has survived the winter of 1894-5. Should it eventually prove perfectly hardy in this country, it will make a grand object in moist, shady nooks in the bog garden or similar place. The flowers are waxy white, with a cluster of yellow stamens in the centre, and often 4 inches across. Its giant leaves are, from 12 in. to 16 in. across, thick and leathery, and borne on stout petioles. The branching stem reaches a height of 3 feet or 4 feet in established plants. Many of the species are easily raised from seeds, but with this remarkable and handsome plant there is yet some difficulty. This no doubt will in time be overcome. At any rate, no plant in this great genus is more worthy the fullest attention of the cultivator at the present time.

ALPINE SPECIES.

Under this head will be found the best of the dwarfer species, the majority of which will be

suitable for the rock garden by reason of their dwarf stature.

*RANUNCULUS ALPESTRIS*.—A true alpine plant of about 4 inches or 6 inches high, with pleasing shining tufts of dark green, roundish, cordate, and sometimes trifid leaves. The plant usually inhabits a calcareous soil in its mountain home, but under cultivation this is not absolutely essential to its success. The flowers are pure white and large in proportion to the growth of the plant, with a cluster of yellow stamens in the middle and usually produced singly on erect stems. It is a fine plant for the rock garden, growing freely in loam, peat and leaf soil in about equal parts. It should be kept moist during the flowering season, which usually begins about June. Native of the Pyrenees and other parts.

*R. AMPLEXICAULIS* (Stem-clasping Crowfoot).—This is one of the best of this genus, and, happily, one of the easiest to cultivate. The plant grows from 6 inches to 12 inches high, the latter only when well established and in good positions. What I have found to suit it best is a compost of peat and loam in about equal parts, planting in a shallow depression where it is always moist. This species and *parnassifolius* are excellent companions for *Corydalis nobilis* and the *Dentarias*, and under these conditions they grow freely. The flowers, produced several on a stem in the early spring months, are of a glistening white, with yellow centre. Seeds are frequently produced, and a good stock may soon be raised. I have often seen this plant on a very dry bit of rockery, but in such places the plant only exists, and would be infinitely better suited in the drier portions of the bog garden or with the plants above-named. It is a native of the Alps of Europe, Provence, Apennines, Iceland, and on the mountains of Leon, in Spain, always in high, moist, rocky situations. Under cultivation moisture seems essential.

*R. ANEMONOIDES*.—Another true alpine, often not more than 3 inches in height though when

*Ranunculus glacialis*.

well established in favourable positions it may sometimes be double that height. A large number of these dwarf-growing species require some time to become established, and for this reason care should be taken to plant them in positions success, and then allow them to develop and

display their charms. The species under notice is one of these. This in some degree is perhaps due to the very small pieces obtainable; but when well established it is one of the most charming plants of the rock garden. What it appears to love best of all is a deep fissure of very gritty loam, with leaves and peat, the latter not absolutely necessary, but helpful in securing in summer-time a condition of coolness that many of these tiny mountain plants delight in. Many of the kinds are greatly assisted by planting their roots in contact with pieces of sandstone rock placed just below the surface. A tuft of this plant, or, better still, a group in early spring in flower constitutes one of the choicest bits of any rock garden flora. The flowers are each about 1½ inches across or nearly so, and are white, tinted with rose-pink, thus forming an exquisite mixture. The charming little plant inhabits the Styrian Alps, Tyrol, &c.

*R. GLACIALIS*.—As may be inferred by its specific name, this species inhabits the loftiest mountain ranges near the limits of the eternal snow. The plant grows about 4 inches high. The leaves are fleshy and of a dark green hue, the upper ones sometimes covered with hairs. The flowers are of a reddish hue suffused with purple, and may readily be distinguished by their very hairy calyx. The plant succeeds best on the higher and more exposed parts of the rock garden in gritty loamy soil, and should be kept moist during the summer. It is quite probable that under cultivation the above plant would succeed best in quite moist spots, as from its position in its mountain home it must be daily supplied for months with moisture from the melting snow. Alps, Pyrenees, and European mountains generally.

*R. GRAMINEUS* (Grassy Crowfoot).—This species is scarcely an alpine, but is included in this group by reason of its dwarf habit. It is about 1 foot high, and is usually surmounted by two or three flowers of a bright yellow. It is better suited for the woodland or wild garden (as it does not figure among the choicer kinds), and for this reason I briefly refer to it here. The plant is sometimes found in Wales in the higher pastures, but always in dry ground. A native also of Southern Europe.

*R. MONTANUS* (Mountain Crowfoot).—This species is of very easy culture in cool, shady places in ordinary sandy loam. The plant grows about 6 inches high and has bright yellow flowers, each about three-quarters of an inch across. The flowers are borne singly on the somewhat downy stem, but near the base the pubescent character is absent. This species may be freely increased by division and also by seed, and may readily be established in moist Grass or similar spots in the garden. Native of mountains of Europe.

*R. PARNASSIFOLIUS* (Parnassia-leaved Crowfoot).—This is one of the most distinct of the dwarf alpine kinds, and is not to be confounded with any other. Inhabiting high elevations in the Alps and Pyrenees, it is generally found in granitic or calcareous soils in the fissures of rocks contiguous to perpetual snow. The thick, entire,

somewhat heart-shaped leaves are very distinct. The flowers are snowy white, about the size of those of *R. amplexicaulis*, and are produced several on stems about 6 inches high. This species may be grown quite successfully in moist, loamy soil in the rock garden in much the same way as recommended for *R. anemonoides*.

*R. PYRENEUS* (Pyrenean Crowfoot).—A distinct species, attaining to nearly a foot in height and inhabiting the highest of the European Alps, more particularly the Pyrenees, where it abounds near the limits of perpetual snow. The leaves are either lance shaped or linear, with the scapes downy at the top. *R. plantagineus* from the Piedmontese Alps, and *R. bupleurifolius*, usually found in moist valleys in the Pyrenees always at a much lower altitude, are varieties of this species. All have white flowers, which appear in May and continue to July, and are of very easy culture, though perhaps second-rate in value.

*R. PEDATUS* (Pedate Crowfoot).—A yellow-flowered species about 1 foot high, and rather abundantly distributed in parts of Hungary, Tartary, and about the river Volga, in Siberia. The leaves are smooth, the radical ones stalked; flower-stem erect, with from three to five flowers.

*R. RUTEFOLIUS* (Rue-leaved Crowfoot).—Another species from the higher Alps. In common with the other species from these high elevations, this one is only some 4 inches or 6 inches high. The leaves are pinnately lobed and the stem usually one-flowered. In the plants I have seen the blooms are white, but I notice the flowers are described as yellow in the "Dictionary of Gardening." In "Alpine Flowers" they are also described as "pretty white flowers with orange centres," and this entirely agrees with the plants I have grown from time to time. The plant is easily grown in moist gritty loam either in pots or in the rock garden. In the latter it should be given a position and soil similar to *R. anemonoides*, taking care to keep the plants fairly moist through the growing season.

*R. SCUTATUS* (Shield-leaved Crowfoot).—A distinct species with large yellow flowers and large, very smooth, kidney-shaped, crenate leaves. A distinctive feature of this plant is that it is without radical leaves, and in this particular differs from those most nearly allied, such as *hybridus*, *brevifolius*, *Thora*, &c. The stem leaves are sessile with the lower ones clasping the stem. It is a native of the mountain woods of Hungary and grows nearly 1 foot high.

*R. SEGUIERI* (Seguier's Crowfoot).—This species grows about 6 inches high, with three-parted leaves, and is more nearly allied to *glacialis* and *alpestris*, though widely distinct from either. Usually the flowers are solitary and rarely as many as two or three on each stem, which is erect. The flowers are pure white, with distinctly rounded petals. Native of the Alps of Provence, Piedmont, and Carniola in rocky fissures.

*R. THORA* (Venom Crowfoot).—The roots of this species are said to be exceedingly acrid and poisonous, and formerly used by the Swiss hunters of wild beasts to poison their darts. It is a yellow-flowered species closely related to *R. scutatus*, but differing from it in always producing long-stalked and very smooth radical leaves. Both these kinds require room to develop their roots, and are of easy culture in moist loamy soil with plenty of grit added. These two as well as those cited under *R. scutatus* are more vigorous in their growth than many of the species from the higher Alps, and for this reason a goodly depth of soil should be given them. *R. Thora* is distributed through Switzerland, Austria, Greece, the Carpathian and other mountains on rocks and in pastures always near the snow-line.

The above will be found among the best of the alpine species for growing in the rock garden or in positions suggested. In those gardens where the choicer kinds are already established, endeavour should be made to raise seedlings, and in this way to form a little colony or group where they may be seen to better advantage. Unfortunately for the cultivator in England, or in-

deed generally in the lowlands, many species are only obtainable when in flower, and digging them up in this condition sadly mars the chances of establishing the rarer species. But once established they present very little difficulty, and many kinds are most charming when in flower. The seeds should be sown thinly as soon as ripe in sandy soil in boxes or pots and not be disturbed for a full year, or they may be sown beneath a thin flat stone on the rockery, but near to the sides so that the seedlings may push forth. Where opportunity offers this method is better than in pots, as the seedlings can grow unchecked, as in their native haunts. Some of the species seed very freely, and others, as *amplexicaulis*, are readily obtained from the dealers in hardy plants.

#### BORDER SPECIES AND VARIETIES.

*RANUNCULUS ACONITIFOLIUS* FL.-PL. (Fair Maids of France).—Without doubt the most charming of the border kinds, growing about 2 feet high when fully developed. But to attain perfection with this plant, it should be put out in deep loamy soil in a moist position and not disturbed for several years. The plant possesses a charmingly neat, attractive habit of growth and the spray-like manner in which the flowers are produced on the stems fits it for use in a cut state in a way such as few plants possess. The plant is very freely covered with its double, pure white, neat, compact blossoms, which are always admired when seen in good condition. Under cultivation the plant always grows best in somewhat holding soils, and if moist so much the better. It is especially suited for autumn planting.

*R. ACRIS* FL.-PL. (Bachelors' Buttons).—This is the double yellow kind frequently seen in cottage gardens. When seen in a large group its rich yellow double flowers are very pleasing. It is about 2 feet high and erect in habit, and though pleasing in the tone of yellow seen in its flowers, lacks the grace and beauty that characterise the last-named kind, and which render it indispensable as a border plant.

*R. SPECIOSUS*.—This is a first-class perennial border kind, though the plant is only rarely seen. The individual blossoms are as large as those of the double Mar-*h* Marigold, and equally effective in the exceeding richness of their golden orange blossoms. The plant delights in a damp, shady spot in rather heavy soil and will here produce large double flowers, that one might be pardoned at first sight for calling it a Mar-*h* Marigold. The habit of growth, however, is quite distinct in the two plants. *R. speciosus* is of semi-procumbent habit, and rarely attains to more than 1 foot in height. It may be increased by division of the roots.

#### GARDEN OR FLORISTS' VARIETIES.

*RANUNCULUS ASIATICUS*.—This is the species which has given rise to the several sections of garden Ranunculi, which were much esteemed by the old florists. They are indeed among the most beautiful of garden flowers to-day, requiring but the observance of a few simple rules to grow them well. One thing should always be borne in mind if we are to succeed with this charming and varied group of garden flowers, viz., that they must be lifted each year and kept in a place secure from frosts if we are to retain them in health and vigour. It is only in the more favoured localities and where the soil is light and warm that these Ranunculi can be left all the winter in the soil and with safety; and where this can be done, the roots, or "claws," as they are also called, are much best when lifted in July and given a thorough drying before replanting in October or November. In all cases this enforced rest is highly beneficial. Where the roots are planted early in the year, say any time during February, the soil should have been prepared in the previous autumn. A perfectly drained as well as light and warm soil is of chief importance; the soil must also be deeply worked and well enriched with short rotten manure. On very sandy soils,

cow manure that has been laid aside for at least six months will be best, on account of its cooling, moisture holding nature in the soil. Trench the soil fully 2 feet deep and work in the manure at the top of the lower spit. Throw the soil up quite roughly, so that frost and air may break it down. In February, if the weather is open, level the ground with a fork and tread it as little as possible, and, if procurable, some very short manure or old potting soil may be scattered over the surface first, or sown in the drills with the roots. Where quantities are grown it is best to plant in shallow drills not more than 2 inches deep, pressing the roots into position with finger and thumb; then cover in and make the surface moderately firm. There is considerable variety in all the sections, but the French kinds are the strongest growers and are wonderfully free-flowering. The Persian kinds have somewhat smaller flowers and are also dwarfer, but still contain many very fine varieties. The Turban Ranunculi are also a varied group and contain some very richly coloured forms. Indeed, the whole of them are well worthy of fuller representation in our gardens, and furnish a rich variety of flowers in the summer. They are especially suited to beds on the lawn and for small gardens, as they occupy but little room. When we consider the ease with which these things are grown and the wonderfully rich and telling effects that may be produced by a few beds of them, it is surprising they are not more grown. In large gardens where beds of separate colours could be arranged they would produce a surprising result in shades of rich vermilion, crimson, pure white, yellow, pink, and, being so remarkably cheap, would prove quite inexpensive in the end. Like many other members of this genus, these varying hybrid strains delight in moisture in the growing season; indeed, this is essential if the flowers are expected in all their brightness. This and a partially shaded position are the greatest aids to ultimate success in the cultivation of these much-neglected, though very beautiful and easily grown, plants.

E. J.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**EARLIEST HOT-BED.**—The time is at hand when the first bed of fermenting material should be made up. This will allow of any excess in heating to subside and due settlement by the end of the first week in January. Those who may have to produce new Potatoes, Horn Carrets, and Radishes in April take care to collect leaves in bulk early in the autumn, and if stable litter has to be used, to mix and sweat them previous to using. Beds that are made up hurriedly with fresh litters material invariably cause no end of trouble, as, although owing to a sudden lowering of temperature out of doors the bottom heat declines to what is considered a safe figure, they as suddenly rise on a return of mild weather, and, in spite of airing by night as well as day, growth appears far too soon and is weak and spindly. It is astonishing how gentle a heat is required to start the tubers and to maintain growth in a healthy condition, and any slight deficiency in the bottom heat can easily be made up should sharp frosts intervene by building up linings to the top of the frames. Still it is of course advisable to have the beds a foot higher all over than is necessary for successional ones for February planting. The great point in building hot-beds is to put on moderate layers of leaves before treading, otherwise they will be spongy, and when the soil is thrown in, the frames will sway on one side, which to say the least looks very unworkmanlike. Let the linings be well trodden and beaten with the back of a five-tined fork at frequent intervals, or they soon collapse when weight is put upon them. If in a few days the heat of the beds is not excessive, the soil may be thrown in and when warmed through the tubers planted. A somewhat light loamy compost ren-

dered porous by the free addition of spent Mushroom manure, and if not in very good heart enriched by a sprinkling of some approved fertiliser, will form a safe and lasting medium. Farmyard manure in any form I do not approve of in the culture of Potatoes in frames and pits, as at this sunless period of the year a firm and consolidated stem growth cannot be secured if such stimulants are used. It is easy to supply the roots with liquid manure when the tubers have formed later on. A depth of about 9 inches of soil is what I allow, this being increased somewhat when the slight earthing up is given. The less earthing is practised with early Potatoes either under glass or on south borders the better, as it can only have one effect, that of excluding sun and air at a time when those important agents are scarce. Planting completed, admit air in small quantities daily when warm, as there is sure to be a certain amount of steam generated and which is best liberated, otherwise it condenses on the sash-bars and then drips into the soil, which is an evil. A few words must be said about varieties. I have tried many sorts, but find none better than Ringleader and Puritan for frames. The latter is somewhat taller in growth, but if the haulm is pinched when a foot high and a few pegs used for keeping the growths away from the glass, all will be well. To follow Ringleader, Sutton's Seedling does well in frames, but the same pinching and pegging must be adopted, or the frames must be raised from time to time by means of bricks placed under the corners. It will pay anyone having spare ground immediately beneath a south wall to prepare it now for the reception of a few early Potatoes in February, as it is easy to protect growth from all ordinary frosts by covering nightly with bags or canvas. I do not advise sprouting the seed much in this early outdoor planting, as sometimes it gets a check. If the sprouts are just formed, that is all that is required.

**CARROTS.**—In a one or two-light box elevated on the warm bed just referred to, sow now seed of an early Carrot for drawing in April. At that time the roots may be thinned and used for soups, and the rest allowed to swell for future use. Some still cling to the old French Forcing, and while admitting that it may be ready for drawing a few days before other sorts, there are so many finer strains of early Carrots, that I have for several years given this small old sort up. The one I rely on is Webb's Market Favourite, a stump-rooted form of exquisite shape, having a very small core and of delicious flavour. Sown at the same time as the well-known Nantes, it is ready for use from ten days to a fortnight earlier. Nantes Horn, however, must not be ignored, as it is a brilliantly coloured, finely-flavoured Carrot, and may even do better with some than other sorts. In regard to the distance between the rows, if no other seed, such as Cauliflower, Cabbage, or Lettuce, is to be sown in the same frame 9 inches will suffice, otherwise a foot must be given, or these quick-growing subjects will smother the Carrots in infancy. The one great evil in associating Carrots and Cauliflowers is that the latter want almost full exposure to the air when as yet the former are in too young and weak a state to stand it, and if once young Carrots become stunted through a check they never again do well. I sometimes give Carrots 12 inches between the rows, and sow Wood's Frame and French Breakfast Radishes broadcast; the joint crops then do very well; but where Radishes are sown between rows of Potatoes in frames, unless a very short-topped variety is planted and extra space allowed, the Radishes in nine cases out of ten are a failure, the Potatoes outgrowing and smothering them.

**GLOBE ARTICHOKE.**—Where my advice was taken, the old stools were well surrounded with long loose litter or, better still, well seasoned Bracken during the early part of November. Owing to the prevalence of wet weather since that date the mulching has become saturated and partly decomposed, rendering a re-mulch necessary. This will preserve the offsets until the

return of better weather and prevent death should severe frost occur. Those off-sets which in case of any contingency were severed from the parent plants and potted up in autumn must be examined occasionally, as damp or drip is apt to injuriously affect the centres. Remove any green crust which may have accumulated over the surface of the pots, and sprinkle freely with lime and wood ashes to dispel damp and sweeten the atmosphere. By no means leave the lights off, but air freely and continuously. J. CRAWFORD.

#### FRUIT HOUSES.

**EARLY PEACH HOUSE.**—If this house was started a weeks ago the buds will now be moving, and fire-heat may be given to raise the temperature 5° to 10° all round. A low night temperature will be conducive to the best results, and the weather must be taken into account. On cold nights 45° to 50° is sufficiently high, and during the day 10° higher, with a few degrees more during sunshine. In large houses or with trees badly ripened, it is an excellent plan to place a bed of warm leaves and manure on the surface to encourage the sap to rise freely. At times it is necessary to force trees that have not been hard forced previously. To such, a little warmth at the start is of great assistance. Trees that have been forced for years force so readily that the above advice is not needed, and more moisture may be given in the way of syringing overhead from the start, as the trees dry more quickly without any fermenting material over the roots. In syringing, avoid too much steaming of hot-water pipes, if these are directly under the trees, as the buds will drop if too hard forced. From the time the house was closed till the beginning of the year very little ventilation will have been necessary, as the little warmth obtained from the sun would promote bud-breaking and do no harm, though the temperature was higher than is advised above. But with increased sun-heat as the days lengthen these remarks do not hold good, as it will be necessary to admit a little fresh air daily to sweeten the atmosphere and dry the trees. This will also strengthen the buds and prevent them dropping. Bud-dropping often occurs at this period of forcing, more especially with the earliest trees. The early American varieties are much subject to it. In their case I have found a brilliant summer, with a good ripening season and ample supplies of moisture at the roots, the best preventive. Previous to the flower-buds opening, a thorough fumigating should be given several nights in succession, as, though the trees may appear free of green or black fly, these increase so rapidly during the flowering that it is well to take precautions to prevent their doing so, as only a few will hinder a free set. As regards moisture, much depends upon the weather, and even when the trees are in bloom it is well in fine weather to damp the stems and old wood with other parts of the house.

**FLOWER-BUDS AND SETTING.**—In advising the removal of buds before they expand, I am aware I am treading on dangerous ground. Many object to it, but I fail to see why the Peach and Nectarine in common with other trees should be allowed to set all the blooms, as it greatly weakens the trees. A judicious thinning assists those required to set to have more room and is conducive to the health of the trees. We do not hesitate to take away bunches of Grapes before they flower, and the Peach bears such an enormous quantity of bloom when in a robust condition, that there is no fear of evil consequences if moderate thinning is resorted to, removing thickly placed flower-buds and doing the work in a careful manner. In the case of kinds which drop badly, as Early Alexander, it may not be wise to thin, as often the fruits of these kinds set on the back buds or those on the small spray, the larger buds or those on strong wood failing to set freely. With regard to setting the fruits, the chief care is to avoid fluctuations of temperature, and with early trees it is necessary to fertilise the bloom to distribute the pollen, doing the work in the early part of the day. I find the best distributor is a

rabbit's tail, as it can be used more lightly than a camel's hair brush. Many good cultivators advise a dry, airy temperature during the setting period. I do not, as long as the trees are dry at the time named. By freely damping the floors, walls, and boles of the trees a much better growth is secured with freedom from red spider and green-fly. Of course, I do not advise overhead syringing when in bloom, but I think injury is often caused and bud-dropping brought on by excessive dryness. Thoroughly watering the borders at the start should tide them over the flowering period, but in case water is necessary or the roots close to the hot-water pipes, it is well to water before the bloom expands, giving tepid water in liberal quantities.

**SUCCESSION HOUSES.**—Pruning, cleansing and preparing for the succession crop will now be the principal work in this department. As regards pruning, there should be no delay. I always endeavour to get all my Peach and Nectarine trees in condition for starting by the end of the year. No matter whether midseason or later kinds, there is a great gain in doing the work early, as insects may then be got rid of more readily, the trees get a longer rest, and one may use stronger measures to get rid of scale before the buds swell. When scale is present apply Gishurst compound freely, using the insecticide stronger for the old wood at the rate of half a pound of Gishurst to a gallon of tepid water, and half the quantity of Gishurst for the new wood, using rain water with a very soft brush. Previous to the cleansing it is well to loosen all ties from the trellis and tie the wood in bundles after the pruning to facilitate cleansing all parts of the house. In pruning do not hesitate to remove gross wood; also giving ample space for next year's growth to develop. In the case of large trees that have filled their allotted space it is necessary to shorten the terminals and thus allow new wood to spring from the base. As the season advances it may be necessary to thin to the best shoots. In replacing the shoots on the trellis after the cleansing, care must be taken not to tie too tightly. Though the ties may look neat now, room must be given for the wood to swell as the growth increases, and when in full leafage the shoots are overlooked and gumming follows. In cleansing do not omit to thoroughly wash all parts of the trellis and give new ties to all parts of the trees.

**LATE PEACHES.**—I place great importance upon the late Peaches. My remarks apply with equal force to those parts of the country where Peaches and Nectarines do not thrive on open walls. Much the same routine is necessary as advised for succession houses. Now is a good time to renew any worn-out trees or to add new varieties, and much better results are secured when the new trees can be obtained of a good size. If home grown trees which have been on walls are planted, it is well to lift carefully and thus save the crop, as if the roots are preserved and there is no delay in removal, the trees will carry a fair crop the next season. There is no better time than the present to secure new material for future planting, as the weather is now open and the season as regards planting all one may desire. The strongest trees are not always the best, those with well-ripened wood with an absence of coarseness being preferable. I prefer what are termed one-year-old trained trees. These may be had good and soon take to the different soil, and may be given plenty of room during the growing season. After the trees are prepared for the next season's cropping, air freely and do not allow the trees to suffer from a warm temperature.

**TREES IN POTS.**—Much depends upon the time these trees are required to fruit. With pot trees of any kind it is well to bear in mind that the best results are obtained from trees given plenty of time. The trees may now be removed indoors, the house having been thoroughly prepared previously by cleansing. If repotting was neglected at the fall of the leaf in the case of large trees, there should be no delay in doing the work. Severe measures in the way of restriction of strong roots must not now be taken if it is intended to force the trees. When trees are brought in-

doors it is well to examine the soil, and if dry, to give a good watering. Trees in unheated houses may be prepared by cleansing, pruning, repotting, or top-dressing, as required. As the cool house is frequently used for Chrysanthemums, it is well to limewash the walls and cleanse paint, to remove all traces of any green-fly the former occupants may have been infested with. Heated houses may be closed on January 1, and the trees will not require much water at the start. Once in ten days will usually suffice, till the buds are breaking freely, with plenty of air during bright sunshine, and a gentle dewing overhead with the syringe twice daily. In severe weather a little warmth in the hot-water pipes will be required, but the night temperature should not exceed 45°, with 10° higher by day during the first month.

**MELONS.**—Those who have every convenience for growing these fruits will now require to make a start to obtain ripe fruit early in May. Early in December I advised the sowing of an early thin-skinned variety for first crop. Such plants should now be making fair progress and be strong enough to plant in a couple of weeks, so that it will be necessary to prepare the house for the plants. For early fruits, pot culture is excellent if there is no check given during the swelling off, as I find pot plants mature the fruit much sooner than those in beds. If grown in 16-inch or 18 inch pots, these should be plunged on a firm base, and, if not over hot-water pipes, will need fermenting material, such as manure and leaves. Melons delight in a high moist temperature from the start, and where the plants are too weak I advise sowing again in 8-inch pots in a brisk heat. These plants will be superior to those named above. In preparing soil for pots or beds, allow a fair proportion of strong loam, some decayed manure and bone meal with old mortar rubble being mixed with the loam. It is now a good plan to sow every three weeks, as by this means a good supply of plants will be always at hand.

G. WYTHES.

## ORCHIDS.

### CATTLEYA CRISPA.

THE number of really good Orchids flowering during August and September, a time when they are useful for exhibiting, is not large and it is a pity this fine old species is not more generally grown. There is no difficulty in its culture, and although the blossoms lack the width of petal desirable in Cattleyas, its free-flowering habit and the number of flowers produced on the spike amply make up for this trifling deficiency. The flowers on various plants of the species differ widely from each other in colour, but each and every one may be styled a fine Orchid. It is a vigorous, free-growing plant, the pseudo-bulbs 8 inches or 9 inches high, each bearing a leaf upwards of a foot in length. On strong plants the spikes carry from five to eight large flowers, the sepals and petals of which are white, the latter beautifully undulated on the edges. The lip is three-lobed, the centre one a good deal elongated, wavy on the edge, the point recurved, the front portion of which is a very bright purple with many radiating lines of a deeper hue. The side lobes are white externally, the inside where they enfold the column being lined with yellow and purple. As mentioned above, *C. crispa* is easily grown and flowered, but, like all in the genus, it requires care to obtain the best results. To get good growth the roots must be well looked after and kept in a healthy condition. The pots should be clean and filled to within a third of their depth with crocks, covering these with a layer of Moss to prevent the water swelling the finer portions of the compost down among them. The peat should be in rather rough lumps, and

only the best quality with plenty of fibre must be used in about equal proportions with clean fresh Sphagnum Moss. Charcoal and rough pieces of crocks about the size of a Hazel Nut may be mixed with this and bedded firmly about the roots in potting.

The early spring is the safest time to repot, and if the roots in the old compost seem fairly healthy it is unwise to disturb them much, relaying them in the new pots and filling up around with the compost. But if, as is too often the case, they have been growing in a heavy, close mass of decayed peat, most of them will be found to have perished or to be far gone. The only thing to be done here is to wash every part of the old soil away with tepid water, cut off all the dead roots and place the plants in as small pots as they can be conveniently got into, watering very carefully and allowing them a little extra heat until new roots are produced. The same may be said

There are a few other varieties, but the above are the most distinct. They are all natives of Southern Brazil, and the flowers last about a fortnight or a little over in good condition if not wetted or kept in too much heat.

**Odontoglossum pulchellum.**—Although not so showy as many other kinds, this elegant species is always welcome, the pure white flowers, with just enough yellow on the lip to show up the rest of the flower, being deliciously scented and lasting a long time in good condition. It is of the easiest culture, thriving well in the cool house with other *Odontoglossums*, and never getting out of health if reasonable attention is given it. It is a restless kind, not unfrequently starting to grow again before the flowers are past, and therefore needing to be well watered at the root all the year round. It soon makes nice, well-furnished plants, and is one of the easiest of all to establish. Pot culture in peat and Moss suits it best. It is a native of Guatemala, introduced in

*Cattleya crispa.* From a photograph sent by Mrs. Fraser, Westfield House, Ipswich.

of newly-imported plants, but healthy, well-established specimens thrive in the usual *Cattleya* house temperature. *C. crispa* is recorded as having flowered in this country nearly 70 years ago, and was sent to Chiswick from Rio by Sir Henry Chamberlain. Among the varieties that have been described and figured in various publications are

*C. CRISPA BUCHANANIANA*, a fine form named in compliment to Mr. J. Buchanan, of Edinburgh. This is larger in all its parts than the type and has a broader, flatter lip.

*C. CRISPA DELICATISSIMA* bears smaller flowers than the type, and has the segments pure white. The centre lobe of the lip has a suffusion of rose and the veins as in the typical form, but these are very faint.

*C. CRISPA SUPERRA* is, as the varietal name implies, a large-flowering and richly coloured form of the type, the blossoms each measuring nearly 8 inches across. This varies in colour a good deal, but I am not aware of any sub-varieties having been specially named. The most attractive forms are those suffused with a soft rosy-purple.

1840, the variety *majus* being larger in all its parts than the type.

**Odontoglossum crispum virginalis.**—This chaste and beautiful variety, without a spot of any colour upon the pure white sepals and petals, frequently appears among imported plants. The forms vary a good deal in size and in the width of the segments, but they are all beautiful and as easily grown as the typical kind. It was first exhibited by Messrs. B. S. Williams and Son, of Holloway, in 1882, when it received a first-class certificate from the Royal Horticultural Society.

**Scuticaria Steeli** (W. G. G.).—This does better in baskets than pots, but best of all upon large blocks of cork or pieces of Tree Fern stems. If you decide to grow your plants in this way, be sure that the blocks are large enough to allow of the free extension of the roots, and that the latter do not suffer from want of water at any time, more especially when in full growth. A little Moss ought to be placed under the plant, which should be firmly wired in position. If you use baskets for the plants, you must form a high cushion of compost for the bases to rest on,

otherwise the points of the young leaves will still enter the compost as you describe, it being natural to this kind to grow with the points of the leaves downward.—R.

**Cypripedium names.**—"Stelis" (p. 463) appears to have fallen into a most unaccountable blunder in his well-meaning remarks respecting *Cypripedium* names. *Ceres*, *Fascinator* and *Medea* are rightly enough the result of crosses between *C. Spicerianum* and *hirsutissimum*, but *Marchioness of Salisbury* and *Charles Richman* are the result of crossing *bellatulum* and a *barbatum* variety. Undoubtedly new names are being constantly given quite unnecessarily.—REGINALD YOUNG, *Liverpool*.

— I notice there is a slight mistake in the note I sent you a short time ago, and which you published in your last issue. *C. Ceres*, *C. Fascinator* and *C. Medea* resulted from crossing *C. Spicerianum* and *C. hirsutissimum*, and *C. Marchioness of Salisbury* is a cross between *C. bellatulum* and *C. barbatum superbum*. However distinct, *C. Marchioness of Salisbury* cannot be more than a form of *C. Charles Richman*, which had been previously certificated.—STELIS.

### SOPHRONITIS.

ANYTHING bright and telling in colour as these charming little Orchids are is doubly acceptable during the short, dull days of winter when everything outside bears a cheerless look. All the species are of small growth, but they are also extremely free-flowering when well established. The species upon which the genus was founded in 1826 by Dr. Lindley is *S. cernua*, and, besides this, there are only two distinct species. Their culture is not difficult provided a suitable temperature is maintained and an atmosphere free from fluctuations. They thrive in a cool house, such as is usual for *Odontoglossums*, but, according to my experience, are better both as regards size and number of flowers in a few degrees more heat and also rather more sunlight than is here afforded. For newly-imported plants this is really necessary, for they will not start nearly so freely in a house where the night temperature ranges below 55°. When received, they require care in handling, so as to keep the little tufts of pseudo-bulbs from falling apart, as they will do if roughly used. A good cleaning is the first thing needful, well sponging every leaf and pseudo-bulb with tepid soapy water: afterwards cut away all decayed parts, being careful not to cut through the rhizome, but simply to take the pseudo-bulbs off with a keen knife, and any that are doubtful looking leave on, as they are easily removed afterwards if decayed, while if sound they may break and serve to make a better furnished plant. Lay them out thinly upon a stage in a warm house and spray them daily in dull weather, twice or three times when bright. The tiny pseudo-bulbs soon fill out, and commence either to emit roots or to grow, and must be placed in whatever receptacles they are to be grown in. They will grow in pots on the stage in the usual way, but will be found to flower more freely if hung up near the light in the small pans now so much used for Orchids. They need only be large enough to take the plants easily. Allow of about an inch margin of compost, which for the first season must only be a very thin layer, or even a slight surfacing of *Sphagnum* over the crocks, which ought in all cases to nearly fill the pans. After one season's growth this may be added to without removing the plants from the pans, and may be the usual mixture of peat and *Sphagnum*, both of good quality. This must be firmly bedded around them with the dibber, and if trimmed off neatly it is much easier to determine when the plants are dry than if

ragged ends of peat or Moss are allowed to stick out. The plants must be kept fairly moist at the roots the whole year through, and no great variation of temperature is needed summer or winter. The only other care required is to keep them free of insects and to see that the pseudo-bulbs are kept steady in their places. If rocking about they will fail to root into the compost, and consequently the growths will be weak. The plants often push a few flowers upon the first-made growths, but always bloom more profusely when well established. If preferred, *Sophronitis* may be grown on blocks of wood, rough pieces of Apple or Birch being as suitable as any, and in this way they have a very natural appearance. A little Moss for the roots to run through is all that is needful, and they must of course be firmly wired on, the blocks being large enough to admit of their extension, as mentioned above.

*SOPHRONITIS CERNUA* is the typical species. It is a very small-growing Orchid, with clustered pseudo-bulbs half an inch in height, each bearing a single broad green leaf only 1 inch or so in length. The blossoms are produced in November or December, about six being the usual number on each spike. The sepals and petals are scarlet, with a yellow lip. It was introduced from Rio de Janeiro in 1826, and the flowers last a long time in full beauty if not wetted or kept in too much heat.

*S. GRANDIFLORA* is much the best in the genus, the rich glowing tints of the flowers being probably unexcelled in the whole Orchid family. The flowers are upwards of 3 inches across, the sepals and petals being bright scarlet in the type, with yellow markings on the lip. The flowers of this kind are produced singly, and not in racemes, as in the last-named. There is a variety of this with rich carmine flowers. It is a native of the Organ Mountains, and was introduced in 1837.

*S. VIOLACEA* comes from the same habitat, and was introduced three years later. It is seldom seen in good condition, or, in fact, at all in collections, yet it is a most desirable and lovely little species. The pseudo-bulbs are only about 1 inch in length, fusiform and fluted, and each bears a single leaf. The flowers, which occur singly, are of a pretty shade of rosy purple. It is the weakest growing of all and not so tufted in habit, being on this account more suitable than the others for cultivation on blocks. H. R.

### MORMODES LUXATUM.

WHERE many plants of this singular species are grown a good deal of variation will be found in the flowers, and all are worth growing on account of their peculiar structure. It is one of the best of its genus, which is nearly related botanically to *Catasetum* and *Monocanthus*. The typical flowers are of various shades of yellow, with a band of brown on the lip. There is also a white variety, *eburneum*. *M. luxatum punctatum* has small spots of red on the sepals and petals. *M. luxatum* thrives best in a warm moist house, and the plants ought to be only sufficiently shaded to prevent injury to the leaves by scalding. They begin to grow early in the new year, and when the shoots are just on the move is the best time to repot. Being a vigorous rooting kind a good deal more substantial compost may be used than for some of the *Catasetums*, and I have seen very good results by using a third of nice fibrous loam in conjunction with the peat and Moss. This must only be for strong, well-established plants, smaller ones being planted in peat and *Sphagnum* only, with sufficient crocks or charcoal to keep the mass open. The pots must be of medium size and should always allow of a good margin of compost, which must be finished just beneath the base of the leading pseudo-bulbs and arranged in a convex mound. This repotting will only be necessary about once in three or four years if a little fresh surface compost is added annually. After re-

potting, the plants must be returned to the warm house and a damp atmosphere kept up about them by syringing between the pots. Overhead watering is dangerous, as the water is apt to lodge in the centre of the new growths, causing speedy decay. As the young pseudo-bulbs begin to form the roots will be very active, and plenty of water must then be given, as often as twice a day being sometimes necessary. They are not constant in their habit of flowering, sometimes pushing up spikes as soon as the growths are complete, at others resting awhile beforehand. But when the growths are complete, whether flowers are showing or not, the water supply must be curtailed, and later on when entirely at rest only enough must be given to keep the pseudo-bulbs plump. At this time the most suitable position is on a shelf near the glass in any structure where the night temperature is kept at about 55°. The leaves are subject to the attacks of scale, and after these have fallen the insects secrete themselves under the scales upon the pseudo-bulbs. Care must be taken to keep these in check, as upon the health of the foliage depends in a great measure that of the entire plant. *M. luxatum* is a native of Mexico, and was introduced in 1842.

***Lælia superbiens* (St. Joseph's Wand).**— This fine species is now in bloom, one spike having seventeen flowers. The long, bare stem tells rather against it, as it is only in large houses that its beauty can be seen, but where there is room for its full development it is very beautiful. Each flower spans about 6 inches; the sepals and petals are rich bright rose, the latter prettily undulated. The lip is similar in ground colour, with stripes of deep crimson, and a yellow centre. *L. superbiens* thrives well on the central stage of the *Cattleya* house, and must have plenty of room. The pots must be fairly large, and as it is nearly always growing and a vigorous-rooting kind it requires plenty of water. It is one of Mr. G. Ure-Skinner's introductions from Guatemala. He found it growing on rocks and in similar positions in 1840.

***Lycaste Skinneri rosea*.**—Among a number of varieties of this well-known and useful species this takes a high position. The flowers are fully as large as in the type, and of a very rich tint of rose on the sepals and petals. The lip is very pale rose, with a profusion of crimson dots. It is a native of Guatemala, and, like the type, is of the easiest culture, thriving well in a cool house if kept free of insects and allowed plenty of water at the roots while growing. A sub variety, *rosea superba*, has even larger flowers, each measuring upwards of 6 inches across.

## KITCHEN GARDEN.

### EATABLE CUCUMBERS.

THERE seems to be a prejudice against Cucumbers not easy of removal. It is true immense quantities are eaten, but the very people who like them the most are frequently among the first to condemn them as being unwholesome or indigestible. It is possible to have Cucumbers really fit to eat and most enjoyable, and equally possible to have them unfit for human food. We are far too fond of big things. When Cucumber plants are doing well, and especially during such a favourable season for frame culture as that just passed, growers are so proud of their crops, that they delay cutting as long as possible, and the consequence is, only overgrown, comparatively tough and really indigestible fruit ever reaches the tables of the owners of the gardens and their friends. Very many frame-grown Cucumbers are also sold in small towns and villages, and seeing that the larger they are the more readily they sell, it is not very surprising that they are left on the

plants longer than is good for them. In some few gardens Cucumbers are really well grown, and are sent to the table in excellent condition, but more often than not they are either bitter or otherwise second-rate. Those great, limp, fat fruits which sometimes take prizes at shows are not nearly so digestible as smaller, quickly-grown fruit cut when yet as brittle as a stick of sealing-wax. Market growers cannot afford to either waste time in the growth of Cucumbers or to leave them hanging on the plants for show, as that takes too much out of the latter; consequently, what they send to the markets are, if eaten within three or four days of cutting, perfectly eatable and wholesome.

As a rule, market gardeners aim to grow everything that is attractive, the question of quality not greatly influencing them in their choice of varieties, but as far as Cucumbers are concerned the variety that best pleases the retailers also happens to be very superior in point of quality. In Rochford's Market Favourite we have what ought to be considered a model variety, yet very few private gardeners think of sowing it. It is neither a long nor a showy Cucumber, but the plant possesses a good constitution, is very productive, and the fruits are straight, moderately thick, furnished with spines, of a good colour, and particularly good to eat. It also possesses the great merit of keeping fairly fresh several days longer than any other variety that I am acquainted with. I have never tried it in frames, but feel certain it would succeed as well in these as the more popular Telegraph, Lockie's Perfection, Tender and True, and such like. We are now being offered a new variety in the form of a cross between Rochford's and Telegraph, and it may be this will prove a decided gain, especially if the quality of the former is joined to the well-known good points in the Telegraph. The next best variety to Rochford's in point of quality is Cardiff Castle, but this, unfortunately, does not attain sufficient length to please the ordinary cultivator.

Undoubtedly the quality of any variety is largely affected by the cultural treatment given. The plants must be in good health, not merely as regards the haulm, but also at the roots, and the fruit be quickly grown, or otherwise the quality will suffer, let the variety be what it may. The haulm may be fresh and green and the plant apparently in the best of health, and yet the root action be faulty, the crops suffering accordingly. Gardeners too often try to keep their plants cropping longer than they should do; whereas the better plan would be to work them hard and root them out directly they give signs of being exhausted. This is what market growers do, and they might be imitated with advantage. Instead of planting a dozen or more plants at one time be content to start with a third of that number, and to sow more seed within a fortnight of planting, aiming to keep up a succession of young plants rather than to have larger batches at one time, with inevitable glut of fruit, and later on thin or insufficient supplies of inferior Cucumbers. Young plants, however, may be quickly spoiled by faulty treatment at the roots. Too much manure and too much soil are the cause of innumerable early failures. If a sufficiently high temperature at the roots cannot be maintained by the aid of hot-water pipes, then the very earliest plants ought to have the benefit of a hotbed of well-prepared stable manure, or this and leaves in mixture, but after March there ought always to be enough heat in the house to obviate the use of bottom heat of any kind. When the roots strike down into a mass of decaying manure and leaves they are soon

attacked by eelworms, and when thus badly galled are not long capable of supporting the plants, the latter eventually flagging, never again to recover. Always commence with quite small mounds of soil of a light loamy character, and keep the roots active near the surface by means of plentiful supplies of water and weekly light top-dressings of loam, decaying manure, or even leaf soil. Allowing the roots to descend freely into the old hotbed material saves much trouble in the shape of watering and liquid manure, but it is a great mistake all the same. Cucumber roots revel in a moist heat, and should not be smothered by either too much soil or by the sediment resulting from a free use of somewhat thick liquid manure. Nitrate of soda at the rate of about half an ounce to a gallon of water answers as well or better than anything I have ever tried, and plants in full bearing require plenty of it. Grand early crops

rapid and quality good. Under this high pressure speed the plants naturally take up and evaporate much moisture, and will fail quickly if this is not supplied to them. Leaving the Cucumbers hanging on the plants an hour after they are fully grown is a waste of energy, and only those intended to be cooked before they are eaten should be allowed to thicken unduly.

W. IGGULDEN.

#### NOTES ON CELERY.

THE past season having been a tolerably favourable one for the growth of Celery—at least, in this part of the country—perhaps a few notes on some varieties grown here may be interesting. As hitherto, Sutton's White Gem and their A 1 (red) were grown rather largely for the earliest supply, and both were satisfactory, for they were solid, crisp, blanched quickly and produced good hearts with little waste. White Pearl (Webb) is a varie-

Fair Maids of France (*Ranunculus acontifolius fl.-pl.*). (See p. 502.)

of Cucumbers are sometimes had from plants in 11-inch or larger pots. The latter should not be unduly exposed to sunshine; frequent top-dressing to the extent of piling it up above the rims of rough fibrous loam and abundance of water and liquid manure should be given, and the plants be fruited similarly to Melons, that is to say, be trained straight up the roof of a forcing house and the laterals heavily cropped, stopping beyond the second fruiting joint.

High temperatures, accompanied by abundance of atmospheric moisture, are what Cucumbers should have, and if the houses containing the plants were less freely ventilated, there would be fewer complaints of the produce being uneatable or unwholesome. If the night temperatures range from 65° to 70°, and seldom fall below 75° in the daytime, an occasional rise to 90° not being objected to, the atmosphere never being allowed to become parched nor the soil about the roots dry, growth of crops will be

gated kind, so much so, that really, for the sake of blanching, earthing up is unnecessary. It is after the style of White Plume—introduced some years ago with a great flourish—but a vast improvement on that variety in every way, being dwarf and stubby, with plenty of heart and few useless outside leaves. It appears to be a favourite with judges at early exhibitions (August), for at our local show it took first prize in good company and numerous entries, and third prize (for not extra well-grown stuff either) at one of the largest, if, indeed, not the largest, of the provincial shows. Perhaps novelty told in its favour in these cases. To follow these, I find none better than Sulham Prize, too well known to need describing. Pink Perfection is more of a novelty, of a beautiful colour, extremely crisp and excellent in flavour, but the variety seems as yet not to be well fixed, and, moreover, appears to be of more delicate constitution than most, being inclined to scald and damp under high culture.

Dobbie's Champion (Red and White) are large and coarse. For winter use, Standard-bearer and

Leicester Red hold their own against all comers. Where the rainfall is as heavy as is the case here, it is not easy to find the kind of Celery that will stand against it and keep well into the spring; but for the latest supply I rely almost entirely on Incomparable Crimson, finding it later in running than any variety I cultivate, and besides it possesses in a marked degree all the good qualities expected in Celery.

The above remarks apply to the supply of a private garden. For marketing I have no doubt the list of varieties would have to be considerably altered, larger, if coarser, kinds being probably more profitable. Besides, many of these enumerated are so exceptionally brittle as to require most careful handling, and this liability to be broken with rough usage would undoubtedly militate against them as reliable market varieties.

J. R.

**A few good Tomatoes.**—Of the many varieties of Tomatoes which have been tried here, as well as seen and tasted in other places visited, I have come to the conclusion that The Peach is far ahead of any of them as regards flavour and for use in a raw state; in fact I grow a larger number of this variety than all the others combined. I am aware it is but seldom grown in large quantities; many growers do not even know it, but why this should be in an age when so many Tomatoes are partaken of in a raw state is a mystery. It is also very distinct. It is small as Tomatoes go nowadays, but under liberal treatment the fruits are borne freely. I would strongly recommend this variety for its excellence where a demand for superior flavoured Tomatoes has to be supplied. Of other comparatively small kinds Horsford's Prelude and Golden Nugget may be mentioned as good and useful for the same purpose. Of larger kinds for exhibition and cooking, there are many more to select from. In this class I have formed a high opinion of Canadian Express as a very early kind. I admit all the fruit borne by it are not of the perfect shape one admires, but it is an enormous cropper of fair quality. Precocity and heavy cropping should ensure it a share of attention. Challenger is better known, an excellent variety in every respect, producing heavy crops of perfect shaped fruit (deeper than Perfection). The quality is also very good. Duke of York is another kind of similar shape to the preceding, but of deeper colour, excellent in every way, and likely to become popular. Add to these a good strain of Perfection, and the selection, half-a-dozen red and one yellow, will be sufficient for all practical purposes in private gardens.—

J. R.

**Horse Radish.**—It is very instructive to learn on the authority of Mr. Mason, of Greenwich, that the chief reason for our importing such large quantities of Horse Radish roots from Holland during the winter is that these Dutch roots are mild as compared with those of home production. It has been generally thought that the British people specially like that hot pungency which characterises slow-grown Horse Radish, but Mr. Mason's evidence is to the contrary, at least so far as town dwellers are concerned. The roots from Holland are so mild relatively, that quite a large quantity can be eaten without any unpleasant heat resulting. That is no doubt an advantage, as in such case the sliced or scraped root shavings can be so much more fully enjoyed. Roots grown under ordinary conditions and in rather dry soil are usually intensely hot, so that very little can be partaken of, and many who would otherwise eat them prefer to let them alone. It is evident that we can grow as mild roots as the Dutch if we only try. We must, however, have deeply trenched, retentive, and highly manured soil, nice clean straight young stems with crowns attached, and dibbled in fairly deep in rows 2 feet apart, or else have slightly raised beds each having three rows of roots  $1\frac{1}{2}$  feet apart, with broad alleys between so that there may be free access to water liberally during the summer. If there were sewage liquid at hand that could be utilised, so much the better. It is only by such

high feeding and abundant watering, that these quickly grown mild Horse Radish roots are produced, and with our immense land and liquid sewage resources there is no difficulty in growing the roots abundantly at home.—A. D.

#### HORTICULTURAL EXHIBITIONS.

“R. H.” (p. 350) writes on the above subject. He is, unfortunately, only too correct in his statement regarding disappointed exhibitors and judges. It has always seemed to me, and I have had some years' experience at horticultural shows, that those who impute dishonesty to the judges show thereby not only their malevolence, but their ignorance. I can safely say that I myself have never, either as committee-man or exhibitor, detected evidences of partiality in the decisions, and I believe judges to be, as a body, as upright a set of men as can be found in the United Kingdom. I am not holding a brief for them, and have no doubt that, if they considered it worth their while, they could fight their own battle ably enough. Neither do I uphold them because I have invariably received distinction at their hands. I have once been disqualified, by mistake I think, and have twice seen a, to my mind, inferior exhibit placed above my own. I do not, however, on that account, nor did I at the time charge the adjudicators with favouritism, but believe their judgment, though not coinciding with my own opinion, to have been carefully considered and unbiassed by partiality. On two occasions, moreover, I have carried off first prize when, according to my estimation, the second prize exhibit was superior to mine.

Many exhibitors seem to think that they cannot be disqualified, unless by *malice prepense*, and are so blinded by inordinate self-appreciation, that the preferment of a rival's stand to their own appears to them an evident proof of disintegrity. It sometimes happens that exhibitors, disappointed by disqualification or by the non-appreciation of their exhibits, bring such pressure to bear on a weak-kneed committee as to cause the latter to dispense with the services of deservedly-popular and fearless judges, and to fill their places with local men whose opinions are, so to speak, more flexible. This, in the interest of horticulture, is greatly to be deprecated. Judges are wanted who have the courage of their convictions and who will not hesitate to disqualify should they consider the regulations not complied with; not men who, fearing to give offence, pass over evident breaches of the rules without comment. Of these two classes of judges the latter would possibly be influenced by a knowledge of the ownership of exhibits, not arrived at by looking at the cards—a breach of etiquette that I have never seen indulged in by judges—but by, let us say, the colour of, or the shape of labels on, a stand of cut blooms. They recognise the stand as belonging to B, an exhibitor who has been winning first prizes in almost every competition for which he has entered. They are inclined to prefer C's stand, but the unvarying excellence of the renowned exhibitor dominates their minds, and the first prize goes to its usual destination. It may be urged that if the system of pointing the blooms had in this imaginary case been carried out the result would have been different, but this does not follow. The inexperienced judge may be led to place a higher value on individual blooms in B's stand simply because he knows that they are B's, and he cannot forget that B has the reputation of staging nothing that falls much short of perfection, and, in consequence, a bloom gets five where four would have been sufficient. To the efficient judges, knowledge of ownership makes no difference. They are not afraid of running counter to public opinion. They base their decisions on the merits of the stands as apparent to themselves, regardless of praise or blame; and this is as it should be.

As a rule, it is impossible for judges to ascertain the names of exhibitors, except by the connivance of the committee-man who accompanies them during their labours. The exhibitors' cards

are usually in envelopes, which, when a decision is arrived at, are marked one, two, or three by the judges, the committee-man then opening the envelopes, and either affixing to them distinctive labels, or passing them to an attendant who carries them to an official who is filling out ornamental prize cards. In some cases the cards are merely laid on their faces, the judges marking the destination of the prizes on the reverse, but the envelope method is the better. Judges should certainly not be admitted into the show-room while the staging is in progress, not because their presence, enabling them to ascertain who are the respective owners of the exhibits, would lead them to a subsequent display of partiality, but because the inveterate grumblers would be sure to attribute anything that might be construed into a suspicion of favouritism to the knowledge gained by the judges by their inopportune entry. As a matter of fact, however, secretaries and committees of horticultural societies are mostly to blame when this happens. Judges are requested to be at the show-room at a certain hour. The same hour is probably advertised as the time at which the show-room will be cleared of exhibitors. But how often is punctuality in this respect observed? I was last year present at a large provincial show, where, at the time announced for the clearance of the room, some of the exhibits had not appeared. The judges arrived at the proper time and were kept waiting in the hall for an hour and a half before they were enabled to commence their duties, while, ere the latter were half completed, the public surged in. As “R. H.” observes, it is quite possible to keep to time. Exhibitors soon recognise when secretaries and officials are not to be trifled with, and act accordingly. Exhibitors should be cleared out of the show-room at the time stated on the schedule. If they have not completed the arrangement of their exhibits, they must take the consequences of their unpunctuality.—S. W. F.

—The season for horticultural exhibitions is fast drawing to a close. It may therefore be well to look back and see what has been gained from a practical point of view by them, and that we may understand more fully the subject before us, let the pecuniary side be left out of the question altogether. Horticultural societies have doubtless done much to foster and stimulate the cultivation of all kinds of garden produce, inasmuch as they have been the means of bringing together the finest specimens from the most successful cultivators in the kingdom. They have also done a great deal to hinder the natural development of some of our most useful plants and flowers. Some there are no doubt who will disagree with me, but those who are well versed in showing must confess that it is no easy task to carry off first honours at some of the leading exhibitions. We will take the Chrysanthemum. How many additional hours are spent to produce a single bloom fit for the exhibition stand; and if we could but know this we should then be the better able to understand the care needed to bring them to that state of perfection. It is not my intention to say anything to discourage the growth of these lovely useful autumn flowers, but rather to further their popularity. To show that employers as a rule have no idea of the time expended in preparing the blooms for the show table, it may be well to give an instance or two of their want of knowledge in this respect. A lady who was looking through the gardens here a few days ago, and who herself had a very large establishment, remarked to me when we were looking through the Chrysanthemums that she had been reading in one of the papers that the flowers on the show table were curled with tweezers, and asked me if such was the case, to which it was necessary for me to explain that flowers as shown were specially prepared for the occasion, and they had to be “dressed;” in fact most flowers were more or less treated in like manner from the Carnation to the Chrysanthemum. She was so shocked with the idea as to remonstrate with the societies for allowing such things to be done, express-

ing her disappointment that what she saw had not been grown naturally, as she had hitherto looked upon them as being natural productions, not works of art. This is no doubt the case with many employers. They see things on the show table, take a fancy to them, and are sadly disappointed because their gardeners are not able to bring them to the same state of perfection as those they saw at the show. Let us again turn our attention to the production of fruit. There certainly can be no artificial surface dressing of these, as such would spoil their appearance. The public, however, look with astonishment on the splendid samples staged, but they little understand the amount of labour and pains that have been spent to bring them to that state of perfection. When we see tanks built for heating manure water to a certain degree to be applied to the hardy fruit trees in the open quarters in order that the soil may in no wise be cooled by its application, it will then be understood why so few are able to compete successfully and how such splendid samples are grown. Again, turning to vegetables; from what we see in some of the monstrosities produced, it is evident to the practical gardener that a great amount of labour must have been expended on them, much more than could be afforded in the general run of places at the present time. Employers go to exhibitions and see these prodigious specimens, and if they happen to be new varieties, maybe will want their gardeners to grow some; but mark their disappointment when, instead of having specimens something like those shown, they only have one about a third in size and not all the same in character. Exhibitions have done much to encourage this sort of thing; but are gardeners benefited thereby? Many unpleasantnesses arise between gardeners and their employers owing to these facts, especially in establishments that are short-handed. Exhibitions, however, have another and, in my opinion, a far more pleasant side, and this is, they bring gardeners together from various parts of the country, and friends meet at these gatherings who would not in all probability see each other for years if such were not the case. It is certainly pleasant to meet old faces, and though we cannot all be competitors, those of us who are out of the running can congratulate our friends on their success or console them in their rebuffs.—H. C. P., *Buxted Park*.

## NOTES OF THE WEEK.

**Mimulus Queen's Prize.**—Nothing in the *Mimulus* line that I am acquainted with approaches this excellent strain, for the plants are remarkably dwarf and extremely free-flowering; in fact the seedlings commence blooming almost as soon as they are through the soil and keep on flowering. The flowers are very beautiful, being variegated in colour and distinctly spotted, reminding one more of spotted *Gloxinias* than anything else. For a damp spot I know nothing to compare with them. All who saw them here last summer were astonished and delighted.—J. R.

**Jaaminum nudiflorum.**—Among the few hardy shrubs that do something to enliven the dull days which see out the dying year, there is none which claims our gratitude more justly than this *Jasmine*. It is one of the many introductions made by Fortune for the Horticultural Society, which have become as common and as well known as many of our native plants. When it was first introduced from the north of China it was considered only suitable for indoor culture, but now, in the middle of December, it brightens up many a street in the suburbs which would otherwise be dreary stretches of brick wall. Although it is destitute of foliage at the time of flowering, this deciduous habit in a climber for small houses is rather an advantage in this damp climate, especially in narrow streets. This year this *Jasmine* appears to be flowering with exceptional freedom, some of the branches being com-

pletely wreathed with the clear yellow, scentless blossoms. Perhaps of all colours yellow is the most effective in dull weather and in dark places.—B.

**Bambusa Veitchi and others.**—I quite agree with "T." (p. 459) as to the variegated appearance produced by the withered edges of the leaves of the above Bamboo. At even a short distance the deception is well maintained, but I cannot see that this defect enhances the beauty of an otherwise pretty and useful plant, and consider that, instead of these withered portions of the leaves being beauty spots, they are a sad disfigurement. The other Bamboo mentioned by "T.," *B. palmata*, as well as many others, such as *B. aurea*, *B. Metake*, *B. falcata*, *B. viridi-glaucenscens*, *B. Simonsi*, &c., all with green foliage pure and simple, with variations in the depth of the greenery, the width and disposition of the leaves and the habit and stature of the stems and wands, ranging up to 18 feet high, are much nobler objects and far more pleasing to the eye than if daubed with any variegation, be it real or sham.—J. R.

**Gustavia pterocarpa.**—*Gustavia* is a tropical American genus belonging to the Myrtle family and comprising several species, which for large stove houses like the Palm house at Kew are valuable both for their fine foliage and their beautiful fragrant flowers. In spite of its relationship to the Myrtles, it is a very different plant indeed from them. The leaves are each 12 inches to 18 inches long by one-third the width, of broadly lanceolate outline, deep green and of leathery texture. The flowers are borne in a short terminal cluster, each flower being 4 inches across, with six rounded, elliptical, concave petals, measuring individually over 1 inch across, and of a soft creamy white. There is a large cluster of yellow-anthered stamens in the centre. The species is a native of the savannahs and forests of tropical America, and was first introduced into Europe by Linden from the banks of the river Mana, in French Guiana. It is an evergreen tree, over 50 feet in height, but it blooms in a small state, as is proved by a plant from 5 feet to 6 feet high which for some weeks past has been flowering in the Palm house at Kew.

**Angræcum eburneum.**—Taken as a whole, the *Angræcum* cannot be included amongst the most easily cultivated of Orchids. To this rule *A. eburneum* is, fortunately, an exception, and it is perhaps the most robust of all the species. Plants imported many years ago give no evidence of enfeebled constitution, and still flower freely and regularly as each winter season comes round. Like most of the *Angræcum*s, this is a native of Madagascar, but it is also found in the Seychelle Islands. The leaves, each about 15 inches long and of a bright, but rather pale green, are remarkably thick and hard in texture and set in two opposite rows on a stout, erect stem. The flower-spikes have the same erect, stiff character as the leaves, and carry numerous flowers. The chief feature of the flower is the large pure white, heart-shaped lip, the sepals and petals being smaller and greenish. The flowers are fragrant, and last from now until February in beauty. A variety known as *virens* is not so fine, the flowers being smaller and the white of the lip not so pure.

**Veitch Memorial medals and prizes.**—At a meeting of the trustees, held on the 20th inst., it was resolved to present the Veitch silver medal to the following gentlemen in recognition of their eminent services to scientific horticulture, forestry, and arboriculture, viz., Mons. Henri Vilmorin, of Paris; Professor Sargent, Director of the Arnold Arboretum, Boston, U.S.A.; Mr. F. W. Burbidge, M.A., Curator of the Trinity College Botanic Garden, Dublin; and Mr. Malcolm Dunn, of the Palace Gardens, Dalkeith. It was also resolved to place at the disposal of the National Rose Society two medals and two prizes of £5 each, one to be competed for at the metropolitan show held at the Crystal Palace, and the other at the northern show to be held at Ulverston. Also at

the disposal of the National Chrysanthemum Society two medals and two prizes of £5 each, to be competed for at the Jubilee exhibition of the society, and one medal and one prize of £5 to each of the following provincial horticultural societies: Ulster, Dundee, and Derbyshire. All communications respecting the Veitch prizes must be sent to the secretary, A. H. Kent, 40, Doria Road, Fulham, S.W., not to the Chelsea firm.

**Protea cynaroides.**—Of the numerous representatives of the South African and Australian floras which a generation ago were among the most valued of indoor plants, there is none perhaps whose disappearance in these latter days one has so much reason to regret as the *Proteas*. Whilst many of them are really beautiful, they are all more or less striking, and differ much from the common run of greenhouse and stove plants. In many gardens—especially those of comparatively recent origin—there is, on account of so much repetition of the same things, a certain monotony in this branch of horticulture which the inclusion of a few old things like this *Protea* would do much to relieve. *P. cynaroides* is a South African plant introduced about a century ago. It is from 2 feet to 5 feet high at the time of flowering, and its unbranched stems are clothed with smooth leathery leaves. The flowers are pale flesh-coloured, and are produced (as in the composites) in a large terminal head. This is surrounded by large bracts that are, perhaps, the most ornamental part of the flower-head, which is about 6 inches in diameter. This plant likes a peaty soil and plenty of moisture; any stagnation at the root, however, is fatal, and care should be taken not to overpot. It requires a greenhouse temperature.

**Senecio grandifolius.**—Perhaps no genus of flowering plants shows greater diversity of habit than the *Senecios* family. The *Senecios* include small herbaceous weeds, handsome greenhouse plants, climbers, and species of almost tree-like dimensions. It is to the latter that *S. grandifolius* (or *S. Ghiesbreghtii*) belongs. In the temperate house at Kew there is a specimen about 12 feet high with a thick woody stem and a branching top, each branch of which is now crowned with a large corymb of yellow flowers. Regarded either as a fine-foliaged or a flowering plant, this is for a large greenhouse one of the most striking winter bloomers we possess. Its large, coarsely toothed, oblong leaves each 1 foot to 1½ feet long, in themselves render the plant worth growing. During December the flowers (which are really clusters of several corymbs, measuring together over 1 foot across) begin to open. These are of a rich yellow and remain for many weeks in good condition. The species is easily increased by cuttings, and for the first two or three years may be accommodated in a pot. If kept longer, however, it ought to be planted out, as it is a gross feeder and the striking proportions of its leaves and flower clusters can only be secured by liberal treatment. It is a native of Mexico and requires little more than bare protection from frost.

**Maxillaria picta.**—This is one of the few species of *Maxillaria* that still retain a certain amount of popularity, although the genus as a whole is but little grown. It certainly deserves a place in any collection, for it is not only one of the most easily cultivated of Orchids, but yields to none in the profusion of its blossoms. The flowers are now at their best, and their sweet, strong perfume renders them particularly acceptable. It is not a showy or brilliantly-coloured Orchid, but is, nevertheless, a very pretty one. The flowers are produced singly on a scape measuring 3 inches to 6 inches in height, and as many as a dozen scapes will spring from a single pseudo-bulb. The sepals and petals are of a soft creamy yellow, spotted with purple, and are very much incurved; the lip is white and also purple spotted. Fully spread out the flower would measure over 2 inches in diameter. The species should be planted in peat and Sphagnum, and may be grown in either pots or baskets. The

latter perhaps are preferable, as they enable the plant to be suspended when in bloom, which on account of the flowers facing downward is an advantage. It is a native of the Organ Mountains, and having been introduced in 1832 is one of the oldest New World Orchids still generally grown. It requires an intermediate temperature, but where that is not available the warmest end of the cool house will do.

**Helmholtzia glaberrima.**—Although at present a rare and little-known plant, this is certainly a useful one for a winter garden or conservatory. I know of no plant whose flowers remain longer in good condition; indeed, they more than rival some of the Orchids in this respect. In the large temperate house at Kew, where several fine specimens are planted out, it has been in bloom for some months past, and will probably continue to flower all the winter. The species is of Iris-like habit, having two rows of sword-shaped leaves 4 feet to 6 feet high and of a deep green. The flower-scapes are erect, a little shorter than the leaves, the flowers being closely packed towards the top in a branching raceme a foot long. The flowers, which individually are three-quarters of an inch in diameter, are, like the flower-stalks and upper bracts, of a pure milk-white. The species, which belongs to the small and obscure natural order of Phylidree, is also known as *Phylidrum glaberrimum*. It was introduced by Mr. Bull, of Chelsea, but its native country is not certainly known, as it came over in a package containing plants from Australia and the Pacific Islands. It is most probably a native of the latter. It is a robust and free-rooting plant, and succeeds much better planted out in good loam than when grown in pots. A cool greenhouse temperature suffices for it.—B.

**Aphelandra nitens**—Among winter-flowering stove plants there are few which do more to brighten the houses at this season than the *Aphelandras*. Of several species we have lately noticed at Kew in flower, the one perhaps which more than any other combines the beauties of leaf and blossom is *A. nitens*. This plant is a near ally of the better-known *A. aurantiaca*. It is a native of Guayaquil, in New Grenada, and was originally introduced by Messrs. Veitch, of Chelsea, through their collector Pearce. It first flowered with them in 1868. The remarkable leaves, ovate, 6 inches long by 3 inches wide, are of a deep vinous-purple beneath, but on the upper side the colour is a dark bronze, and so glossy as to suggest its having been coated with varnish. The spike is erect, 7 inches to 8 inches high, and terminates the branch on which it is borne. As in all the *Aphelandras*, it is made four-sided by the shape of the numerous, keeled, closely adpressed bracts which clothe it, and from the axils of which the flowers spring. The corolla is a bright scarlet, 1 inch to 1½ inches in diameter, the upper petal narrow and erect, the three lower ones obovate, the middle one the largest. A group of several plants produces a fine effect in the Begonia house at Kew. The *Aphelandras* require to be grown in a moist stove, and, on account of their propensity to become leggy, should be frequently started afresh from cuttings. Perhaps the most satisfactory method is to grow them with a single stem, producing one spike of flowers. When in bloom the flowers keep better if the plants are grown in an intermediate temperature.

**Reinwardtia tetragyna.**—Of the two species of *Reinwardtia* in cultivation—viz., this and *R. trigyna* (both also known under the generic name of *Linum*)—the former is the more valuable as a greenhouse plant. The two species are closely allied, and more than one botanist has expressed the opinion that they are merely forms of one species. The characters to which the specific names refer (that of the number of styles in each flower) do not in every case hold good; instead of there always being four styles in *R. tetragyna*, as the name implies, there is frequently one more or less than that number. A better distinction is afforded in the corolla, which is larger than that

of *R. trigyna* and of a paler golden yellow; the pointed, toothed leaves are also larger. It is a common plant in certain districts of India, and there attains a height of from 2 feet to 4 feet. It is of bushy habit and suckers freely. The leaves are crowded at the top of the branches, where also the flowers are produced; each flower is 2 inches to 3 inches in diameter, and a succession of them is kept up for a long time. The species likes a warm greenhouse or intermediate temperature, and should be grown in a rich compost of loam, leaf-soil and silver sand. The *Reinwardtias*, besides their value as greenhouse plants, are interesting as belonging to that class of plants the cross-fertilisation of which is effected, or rather governed, by the different relative lengths of the styles and stamens in different flowers. *Primula* and *Forsythia* are also familiar examples where short and long-styled flowers occur. By thus hiding away, as it were, either the male or female organs, cross-fertilisation is almost as surely effected as it is in plants that are unisexual.

**Ansellia africana.**—With the exception of the *Angræcums* and other genera of closely allied characters (*Acranthus*, &c.), the continent of Africa has not as yet supplied us with any large number of handsome and useful Orchids. Among the few, however, a high place must be accorded this *Ansellia*, now, unfortunately, a somewhat rare Orchid. Over fifty years ago it was discovered by Mr. John Ansell at Fernando Po growing on the stems of the Oil Palm (*Elais guineensis*). Dried specimens were sent to Dr. Lindley, who named it after its discoverer, and shortly afterwards it was introduced and flowered, a figure appearing in the *Botanical Register* for 1846. The stems of this Orchid vary in length from 2 feet to 4 feet, and are scarcely the thickness of a man's finger. The leaves, confined to the upper part of the stem, are each 9 inches long, with five prominent ribs. The panicles are terminal and branching, forty to fifty (or, on exceptionally fine specimens, eighty to one hundred) flowers occurring on each. They are not only very handsome, but last at least six weeks in good condition, and this at the dullest midwinter season. Each blossom is 2 inches across, the ovate sepals and petals being pale yellow, but thickly blotched with reddish brown; the lip is yellow and unspotted. Of several varieties, the one discovered in the Upper Nile regions and called *nilotica* is perhaps the finest, the flowers being larger and of a deeper yellow. Coming from low levels in tropical regions, this species naturally requires warm moist treatment. It should be potted in fibrous peat and a little Sphagnum and given abundance of water when growing. It is a light-loving plant, and the nearer it can be placed to the glass the better.

#### PHOTOGRAPHIC COMPETITION, 1895.

We thank those who have forwarded photographs for their kind co-operation and the many beautiful things they have sent us, which show a distinct improvement in all ways on those of previous years. The causes of failure are usually over-exposure, getting the distant parts out of tone and all sometimes black, overcrowding of subjects—too much in the photographs, with consequent over-reduction of foliage and flowers.

#### LIST OF AWARDS.

CLASS I.—COUNTRY HOUSES AND FLOWER GARDENS.—Miss E. Willmott, Warley Place, Great Warley, Essex.

#### Extra Prizes.

Mr. Walter Rossiter, 5, Pulteney Street, Bath. Hamswell House; The Terrace, St. Catherine's Court, and Prior Park, Bath; Kingston House; Upper Terrace, Hamswell House.

Mr. G. Fowler-Jones, Quarrybank, Malton, Yorks. Views of Conover Hall, Shrewsbury; Brodie Castle, near Forres, N.B.; Sea Park, Forres, N.B.; and Cawdor Castle.

Mr. W. B. M. Patterson, Nicolls Cottage, Monifieth, near Dundee, N.B. "Cottage," Longforgan, Perthshire; Flower Garden at Bowhill.

Miss J. Allan, Suffolk House, Duppas Hill, Croydon. Two views of a house at Rowfant, Sussex.

Mr. H. Barber, 4, Lime Tree Hill, Matlock Bridge. Stanton Woodhouse; Castle Howard.

Mr. L. G. Linnell, 22, Upper King Street, Leicester. Two views of Turvey Abbey.

Rev. W. A. Woodward, Flax Bowton Rectory, R.S.O., Somerset. Arley Cottage, Staffordshire; Lyntesfield, Somerset.

CLASS II.—FLOWERING PLANTS.—Mr. S. W. Fitzherbert, Lauscombe House, Torquay.

#### Extra Prizes.

Mr. E. H. Woodall, St. Nicholas' House, Scarborough. Three *Vandas*, *Astericus maritimus*, *Cycnoches chlorochilon*, *Lilium testaceum*.

Mr. C. Metcalf, Mill House, Halifax. *Begonia Rex*, *Pyrethrum uliginosum*, *Clematis John Kenneth*, *Belladonna Lilies* in a vase.

Mr. J. Henri, 8, Park Villas, Maidenhead. *Dahlia Guiding Star*, *Fritillaria Meleagris*, *Pyrethrum Mont Blanc*, *Hoya carnosae*.

Mr. R. Wallace, Colchester. *Lilium Parryi*, *Calochorti*, *Hemerocallis aurantiaca major*.

Mr. W. S. Rogers, 25, Sloane Street, London, S.W. *Narcissus Bulbocodium*, *Chrysanthemum Miss Rose*, C. Miss Anderson.

Miss Gaisford, Offington, Worthing. *Lagerstræmia indica*, *Xanthoceras sorbifolia*, *Cassia corymbosa*.

Lt.-Col. Kelsall, 23, Waltham Terrace, Blackrock, Dublin. *Campanula isophylla*, *Solanum jasminoides*, *Spiræa flabelliformis*.

Mr. Walter Rossiter, 5, Pulteney Street, Bath. *Polyanthus* and *Primrose*, *Brugmansia suaveolens*, *Moutan Tree Pæonies*.

Mr. W. J. Vasey, Broad Street, Abingdon. *Chrysanthemum Etoile de Lyon*, *Begonia*.

Mr. Peter Terras, Markinch, Fifc, N.B. *Picoetes*, *Rhododendron*.

Rev. W. J. Gerrard, The Rectory, Rathangan, Ireland. Group of Sunflowers.

Mrs. E. M. Kendall, Gatley Hill, Cheadle, near Manchester. The "Plantation."

CLASS III.—BEST GARDEN FRUITS.—Mr. J. Henri, 8, Park-villas, Maidenhead.

#### Extra Prizes.

Mr. J. Miller, 14, Fox-street, Rothwell, Northampton. King of the Damsons, Apple White Summering.

Mrs. T. W. Robinson, The Cedars, Kingswinford, nr. Dudley. Pear *Catillac*, Pear *Baurré Superfin*.

Mr. Chas. Seabrooke, The Echoes, Grays, Essex. Pear *Durondeau*, *Pyrus japonica*.

Lt.-Col. Kelsall, 23, Waltham-terrace, Blackrock, Dublin. Apple *Kentish Fillebasket*.

CLASS IV.—ALPINE FLOWERS AND ROCK GARDENS.—Miss E. Willmott, Warley Place, Great Warley, Essex.

#### Extra Prize.

Mrs. Selve Leonard, Hitherbury, Guildford. *Primula marginata*, *Narcissus triandrus*, scene in alpine garden, *Primula denticulata* alba.

CLASS V.—LAWNS AND LAWN TREES.—Mr. Magnus Jackson, 62, Princes-street, Perth, N.B.

#### Extra Prizes.

Lord Annesley, Castlewellan, Co. Down, Ireland. *Osmanthus myrtifolius*, *Aralia spinosa*, *Cupressus nutkaensis*.

Mr. W. M. Smith, Clarence Lodge, St. Luke's, Cork, Ireland. Lawn fernery, a lawn at Castle-martyr, lawn shrubs at Ashbourne.

Miss Knox-Gore, Ardmore, Torquay. Two views of the lawn at Beleck Manor, Dracanas on Lawn.

CLASS VI.—HERBACEOUS BORDERS.—Mrs. Martin, Bournbrook Hall, Birmingham.

*Extra Prizes.*

Mr. Lawrence G. Linnell, 22, Upper King Street, Leicester. Flower Border at Lovat, Terrace Border at Turvey, Flower Border near Mission House.

Mrs. Deane, Fairfields, Farcham, Hants. A Herbaceous Border.

CLASS VII.—WATER GARDENS.

Nothing of merit.

CLASS VIII.—BEST VEGETABLES.—Mr. F. Parren, 38, Northgate Street, Canterbury.

*Extra Prizes.*

Mr. J. Miller, 14, Fox Street, Rothwell, Northampton. American Winter Squash, Vegetable Marrow, long, variegated.

Rev. W. J. Gerrard, The Rectory, Rathangan, Ireland. Vegetable Marrow.

CLASS IX.—PLANS OF FLOWER GARDENS.

Nothing of merit.

CLASS X.—TABLE DECORATIONS.—Mrs. Martin, Bournbrook Hall, Birmingham.

**The Royal Gardeners' Orphan Fund.**—

The usual monthly meeting of the general committee took place at the Horticultural Club on the 20th inst., Mr. William Marshall in the chair. The secretary announced that the sum of £105 15s. 10d. had been received from the trustees of the William Thomson Memorial Fund, they agreeing to the terms as to voting in respect thereof proposed by the committee. The following special donations were announced: Mr. H. J. Jones, Ryecroft Nursery, Lewisham (donations from visitors inspecting Chrysanthemum house), £10 12s. 7d.; The Scottish Horticultural Association (per Mr. R. W. E. Murray), £5; Mr. H. Herbst, Kew Road, Richmond (box), £2 11s. 6d.; Mr. G. W. Cummins, The Grange Gardens, Carshalton, £2 10s.; Mr. W. R. Bloxham, Chesterfield, £2 2s.; The Market Harborough Horticultural Society (sale of flowers at Chrysanthemum show), £1 15s.; Mr. R. Ingleby, Chesterfield, £1 7s. 6d.; Mr. C. Gibson, Morden Park Gardens, Mitcham (box), £1 1s. 7d.; Mr. J. Mc Kerchar, Holloway, £1 1s.; Croydon Chrysanthemum Society (sale of flowers), per Mr. W. P. Beckett, £1 1s.; Messrs. R. W. Proctor and Son, nurserymen, Chesterfield (sale of flowers), £1 1s.; Kingston Gardeners' Association, £1; and the following from boxes: Mr. W. Bates, Twickenham, 18s. 6d.; Mr. F. Miller, Margate,

18s. 2d.; Mr. T. Newbould, Cragg Royal, Leeds, 17s. 6d.; Mr. A. J. Brown, Chertsey, 15s. 6d.; Miss Emily Roger, Farnborough, 13s.; Mr. W. H. Divers, Belvoir Castle Gardens, Grantham, 13s. 7d.; Mr. Jas. Day, Galloway, Garlieston, 12s.; and Messrs. H. Cannell, 10s. A further sum of £500 was ordered to be invested, and a cheque for the quarter's payments to the sixty children upon the fund (amounting to £195) was paid. It being reported that during the coming year nine children would cease to derive benefit from the fund, having reached the maximum age, it was resolved that ten children should be elected at the annual meeting to take place at Anderton's Hotel, Fleet Street, on February 21 next. The *bona fides* of a number of candidates for election were passed, and the proceedings closed with a vote of thanks to the chairman, who thanked the members of the committee for their attendances and support during the year.

**The weather in West Herts.**—A cold week. On three days the highest shade temperatures ranged only between 34° and 36°, and on the night preceding the 22nd the thermometer exposed on the lawn showed 13° of frost. During the week the temperature of the soil at 2 feet deep has fallen 2°, and at 1 foot deep 3°. At the latter depth the reading is now 2° below the mean for the month. Snow fell on the 20th and 25th, and on the morning of the latter covered the ground to the depth of 1¼ inches. For 131 hours during the week the direction of the wind has been some point between north and east. During the six days ending the 21st no sunshine at all was recorded.—E. M., *Berkhamsted*.
